## Executive Summary

## Introduction and background

The Scottish Schools Adolescent Lifestyle and Substance Use Survey (SALSUS) is a continuation of a long established series of national surveys on smoking, drinking and drug use. It is the Scottish Government's main source of prevalence data on adolescent substance use. The data on substance use is collected alongside other contextual lifestyle, health and social factors.

This report explores trends in mental health and wellbeing and explores the factors which best predict higher and lower mental health and wellbeing. All differences commented on in the report are statistically significant.

## Changes in mental health and wellbeing over time

The 'Strengths and Difficulties Questionnaire' (SDQ) has been included in SALSUS since 2006. This is a standard measure of mental health and wellbeing and gives a measure of overall mental health and wellbeing along with scores for five separate scales. The 5 scales cover emotional symptoms, conduct problems, hyperactivity/inattention, peer relationship problems, and pro-social behaviour.

Overall SDQ scores have remained fairly constant over time among young people in Scotland. However, once this is broken down by individual SDQ scales, the picture becomes more complicated.

Fewer young people have conduct problems in 2013 compared to 2006 and, similarly, prosocial behaviour has been improving gradually since 2006. There has also been a small decrease in hyperactivity. In contrast, emotional problems, and to a lesser extent peer problems, have worsened over time, with the main change happening between 2010 and 2013.

One of the most important findings is the striking difference in results for 15 year old girls in the last 3 years when compared with the other demographics groups. This group appear to be suffering much poorer mental health and wellbeing than the other groups, particularly in relation to emotional problems - borderline and abnormal scores rose from 28\% in 2010 to $41 \%$ in $2013^{1}$.

In terms of overall mental health and wellbeing, in 2013, 39\% of 15 year old girls were abnormal/borderline on the SDQ scale. In 2010, the corresponding figure was $29 \%$. This difference is statistically significant.

Since 2010, SALSUS has also included the Warwick-Edinburgh Mental Wellbeing Scale (WEMWBS). This is a standard tool that measures mental well-being based on responses to 14 statements. WEMWBS scores have remained reasonably stable between 2010 and 2013. However, there was a slight decrease in the average mental wellbeing score among 15 year olds girls.

[^0]Two other surveys show similar findings. The Scottish Health Survey and the Scottish element of the cross-national Health Behaviour in School-aged Children (HBSC) Study also both find that mental health and wellbeing deteriorates with age and girls have worse mental health and wellbeing than boys.

## Profile of mental health and wellbeing in 2013

Many factors showed an association with emotional and behavioural problems and, in most cases, an inverse relationship with mental health and wellbeing. However, there were two main areas that emerged as key to pupils' mental health and wellbeing:

- The number and nature of pupils' friendships - those who had fewer friends had poorer mental health and wellbeing e.g. 75\% of girls with no close friends had a borderline or abnormal overall SDQ score, as did those with older friends e.g. 17\% of pupils who had friends their own age had a borderline or abnormal conduct problems score compared with $41 \%$ of pupils with mostly older friends.
- The pupils' relationship with school - those that disliked school, felt pressured by school work, truanted on multiple occasions or had been excluded had poorer mental health and wellbeing than those that did not.

Other factors that were associated with increased prevalence of poor mental health and wellbeing included:

- Mother's knowledge of activity being below average
- Spending 6-7 nights a week out with friends.

Variables that were linked to better mental health and wellbeing included:

- Living with both parents
- Expecting to go to university after leaving school
- Belonging to a group or club.

A number of activities appeared to have a protective effect against poor mental health and wellbeing (although causal links are likely to be complex). Belonging to a group or club and seeing friends, doing a hobby, reading books or playing a sport at least weekly were associated with better mental health and wellbeing. For girls in particular, playing sport on a weekly basis was strongly related to lower levels of emotional and behavioural problems.

## Predictors of mental health and wellbeing

Girls were more likely than boys to have borderline or abnormal scores for the overall SDQ scale, emotional problems and hyperactivity. However, boys were more likely than girls to have problems with conduct, peers or pro-social behaviour.

The relationship between age and mental health and wellbeing is not straightforward. Emotional and behavioural problems appeared to increase, while mental health and wellbeing decreased, as pupils moved further into adolescence.

Overall, poor mental health and wellbeing is more prevalent among S4 than S2 pupils. However, age did not come out as a significant factor in the modelling of the overall SDQ score. Age, by itself, is not a key driver of mental health and wellbeing. Instead, it reflects
the prevalence of other drivers changing as pupils get older. Most notably, S4 pupils are more likely than S2 pupils to feel pressurised by schoolwork and to not like school.

Poorer physical health is associated with lower mental health and wellbeing. Pupils who reported that they had a limiting illness or disability tended to suffer from poorer mental health and wellbeing.

Pupils who had a mixed or multiple ethnicity were more likely to suffer from poor mental health and wellbeing than those from other ethnicities.

Higher levels of deprivation were correlated with poorer mental health and wellbeing. The Scottish Index of Multiple Deprivation (SIMD), perceived family affluence, and receipt of Free School Meals all showed a relationship with mental health and wellbeing. Perceived family affluence had a stronger association than the geography based measure of deprivation (SIMD) and receipt of Free School Meals.

However, the impact of deprivation was not as large as some other factors such as attitudes to school. Pupils who thought that their family was not well off were twice as likely as those who thought that their family was very or quite well off to have borderline or abnormal scores for the overall SDQ. Pupils in the most deprived quintile of SIMD were $50 \%$ more likely than those in the least deprived quintile to have borderline or abnormal scores for the overall SDQ. In contrast, pupils who said that they did not like school were over four times more likely to have borderline or abnormal scores than those who said that they liked school a lot.

There was no clear pattern in mental health and wellbeing by urban/rural classification.

## 1 Background and methodology

## Policy background

The Scottish Government's Mental Health Strategy 2012-2015 outlines mental health policy for children and young people across several priority areas. It takes forward action points from the preceding 'Delivering for Mental Health 2006' and 'Towards a Mentally Flourishing Scotland: Policy and Action Plan 2009-2011'.

Policy in this area aims to develop child and adolescent mental health services that are directed at the care needs of this group. For example, the strategy addresses the specific mental health care needs of children and young people by setting out policy on attachment issues and by making basic mental health training more widely available to professionals in the children's services workforce and improving access to child psychotherapy by investing in a new cohort of trainees.

The Mental Health Strategy is informed by national indicators for child and adolescent mental health (2012) developed by the Scottish Government and NHS Scotland. The national indicators cover mental health problems, mental wellbeing and associated contextual factors such as learning and development and equality. The indicators are aligned with other initiatives directed towards the wellbeing of children and young people such as the Early Years Framework, Curriculum for Excellence, Equally Well and Getting it Right for Every Child.

The Scottish Government is working alongside a range of stakeholders to develop a children and adolescent mental health services scorecard to collect data on the provision of mental health care for children with learning disabilities, and identify areas where there is limited access to care, in order to base targeted interventions. The strategy details targets to improve accessibility of specialist child and adolescent mental health services by reducing waiting times after referral to a maximum of 18 weeks. Furthermore the Strategy details policy to reduce under 18s admission to adult wards.

Policy areas that stem from the mental health strategy include working more effectively with families and carers, embedding more peer-to-peer support, increasing support for self-help approaches, extending the anti-stigma agenda through the 'see me' programme, focussing on the rights of those with mental illness, developing the outcomes approach to include personal and social outcomes and ensuring that technology is used effectively to deliver evidence-based services.

## Survey background and purpose

1.1 The Scottish Schools Adolescent Lifestyle and Substance Use Survey (SALSUS) is a continuation of a long established series of national surveys on smoking, drinking and drug use (Figure 1.1). These were carried out jointly in Scotland and England between 1982 and 2000, to provide a national picture of young peoples' smoking, drinking, and drug use behaviours within the context of other lifestyle, health and social factors.
1.2 Since 2002, Scotland has developed its own, more tailored, survey known as SALSUS. SALSUS measures progress towards Scottish Government targets for smoking and drug use, and is used to inform the Scottish Government priority of addressing harmful drinking among young people. The survey series also provides local prevalence rates for smoking, drinking and drug use across Alcohol and Drug Partnerships (ADPs), local authorities and NHS Boards. SALSUS data are used in a number of the ADP national core indicators, which allows them to monitor their progress against a common set of outcomes. ADPs and their community planning partners make extensive use of SALSUS data in local needs assessments and in developing their strategic priorities.

Figure 1.1 - History of SALSUS and its predecessors

Full access to the 2013 results can be found
here: http://www.isdscotland.org/Health-Topics/Public-
Health/SALSUS/Latest-Report/.

## Methodology

1.4 SALSUS is a confidential, self-completion questionnaire that is completed by S2 and S4 pupils, average age 13 and 15 years, in school (previous waves surveyed S1-S4). The survey covers items on smoking, drinking and drug use, as well as a number of contextual questions about lifestyle.
1.5 Since 1990, the datasets from SALSUS and its predecessors have been deposited in the UK data archive. The Scottish Government commissioned Ipsos MORI to examine the feasibility of combining these datasets into a single dataset to facilitate greater use of this resource, and, if it was deemed
feasible, to create a unified dataset together with accompanying documentation. Changes in the methodology and questionnaire coverage were examined.
1.6 We concluded that the data was consistent enough that a combined dataset would allow meaningful analysis of trends over time. This combined dataset has now been constructed and this report is one of the first uses of this data source.
1.7 All differences commented on in the report are statistically significant.

## Mental health and wellbeing indicators

1.8 SALSUS is foremost a survey about substance use in adolescence and the outputs are therefore focussed on prevalence of smoking, drinking and drug use. However, the survey contains a wealth of information on the behaviour of young people in Scotland over the last 30 years. While these variables are reported on in terms of their relationship with substance use, they have never been reported in their own right.
1.9 This report explores one of the other topics included in SALSUS - mental health and wellbeing. It covers trends in mental health and wellbeing, the profile of those with poorer mental health and wellbeing in 2013, and the factors which best predict positive mental health and wellbeing.

## Emotional and behavioural problems - Strengths and Difficulties Questionnaire

1.10 The 'Strengths and Difficulties Questionnaire' (SDQ) was designed by Robert Goodman (1997) ( 1 - see Reference section) and is widely used by researchers, clinicians and education professionals. This measure has been included in SALSUS since 2006. The questionnaire comprises 25 items that are grouped into 5 scales, with each scale including 5 questions. The scales are:

- emotional symptoms (5 items)
- conduct problems (5 items)
- hyperactivity/inattention (5 items)
- peer relationship problems (5items)
- pro-social behaviour (5 items).
1.11 Information on how to score the self-completed SDQ was obtained from the website http://www.sdqinfo.com, a site referenced by Goodman et al. For each item in each of the five scales, the value of the responses 'Not true,' 'Somewhat true,' and 'Certainly true' are assigned a value from 0 to 2.
1.12 Overall scores were calculated for each of the five scales by summing the scores for all items within each scale. Total difficulties scores were also calculated as an overall measure of emotional and behavioural problems by summing the scores for emotional problems, conduct problems,
hyperactivity and peer problems, but excluding scores for pro-social behaviour.

## Mental Wellbeing - Warwick-Edinburgh Mental Wellbeing Scale (WEMWBS)

1.13 The Warwick-Edinburgh Mental Well-being Scale (WEMWBS) was developed by researchers at the Universities of Warwick and Edinburgh, with funding provided by NHS Health Scotland, to enable the measurement of mental wellbeing of adults in the UK (2).
1.14 Since 2010, SALSUS has included WEMWBS. Developed as a tool for measuring mental wellbeing at a population level, the scale comprises 14 positively worded statements that relate to an individual's state of mental wellbeing (thoughts and feelings). Pupils were asked to indicate how often they have had such thoughts and feelings over the last two weeks. Each statement has a five item scale ranging from ' 1 - None of the time' to ' 5 - All of the time'. The lowest possible score is therefore 14 and the highest is 70 .

## 2 Changes in mental health and wellbeing over time

## Key Findings

- Overall SDQ scores have remained fairly constant over time among young people in Scotland. However, once this is broken down by individual SDQ scales, the picture becomes more complicated.
- Emotional problems, and to a lesser extent peer problems, have worsened over time with the main change happening between 2010 and 2013.
- In contrast, conduct problems and pro-social behaviour have been improving gradually since 2006. Hyperactivity has marginally improved.
- One of the most important findings is the striking difference in results for 15 year old girls in the last 3 years when compared with the other demographic groups. This group appears to be suffering much poorer mental health and wellbeing than the other groups, particularly in relation to emotional problems - borderline or abnormal scores rose from 28\% in 2010 to $41 \%$ in 2013.
- WEMWBS has remained reasonably stable between 2010 and 2013. However, there was a slight decrease in the average mental wellbeing score among 15 year old girls.

## Wider context of mental health trends among adolescents

2.15 In March 2012, NHS Health Scotland published a core set of national, sustainable mental health indicators for children and young people in Scotland (3). The aim of the indicators was to "support and promote consistent and sustainable national monitoring of the state of mental health and the associated contextual factors for children and young people in Scotland and [...] to create a mental health profile for children and young people in Scotland" (3).
2.16 A number of these indicators stem from data collected in SALSUS using the Strengths and Difficulties questionnaire and WEMWBS. Almost all of the analysis in this report will coincide with these indicators.

## Overall mental health and wellbeing trends

2.17 Since 2006, the proportion of pupils with an abnormal overall SDQ score has slightly increased (Figure 2.1). However, when broken down by age group and gender a slightly more complicated picture emerged.

Figure 2.1 Overall SDQ score between 2006 and 2013

2.18 The proportion of 15 year old girls who have a borderline or abnormal SDQ score has been higher than any other group since SDQ was added to the survey in 2006. However, since 2010, this gap has widened. The proportion of 15 year olds girls who have borderline or abnormal scores increased by 10 percentage points between 2010 and 2013. Overall, nearly 4 in 1015 year old girls had a borderline or abnormal SDQ score in 2013 (Figure 2.2).

Figure 2.2 - Trends in overall SDQ scores by sex and age (\% borderline or abnormal score)

1 Full bases in Table A. 1 in Appendix A
Trends in individual SDQ scales
2.19 The overall SDQ score gives an overview of emotional and behavioural problems. However, there is a great deal of variation in trends across the individual components that do not necessarily follow the pattern of the total difficulties score (Figure 2.3).
2.20 While the overall SDQ score has changed little over time for all pupils, the individual scales show differing patterns. Pro-social behaviour has been improving over time. Unlike the other SDQ scales this has been a gradual change, rather than largely due to differences between 2010 and 2013
(Figure 2.3). Full trend charts for each individual scale are available in Appendix B.
2.21 The emotional difficulties scores have worsened over time, although this has predominantly happened between 2010 and 2013. In contrast, conduct problems scores showed a more positive picture. The proportion of those with a normal score has been increasing gradually between 2006 and 2013.
2.22 Levels of hyperactivity have remained fairly stable over time, with a slight reduction in abnormal scores. Difficulties with peers have increased over time. Again, this has predominantly happened between 2010 and 2013 (Figure 2.3).

Figure 2.3 Individual SDQ scales between 2006 and 2013 (\% borderline or abnormal score)

## Emotional problems

2.23 The overall increase in emotional problems has mainly been driven by an increase in borderline or abnormal scores among 15 year old girls and, to a lesser extent, 13 year old girls. This change has considerably widened the gap in emotional difficulties between boys and girls (Figure 2.4).

Figure 2.4 - Trends in emotions SDQ scores by sex and age (\% borderline or abnormal score)

I Full bases in Table A. 2 in Appendix A
I

## Conduct problems

2.24 Among both age groups, boys were more likely to report conduct problems than girls. Conduct problems have been decreasing among all groups and the gap between boys and girls has remained constant (Figure 2.5).

Figure 2.5 - Trends in conduct SDQ scores by sex and age (\% borderline or abnormal score)

Hyperactivity
2.25 The pattern of change in levels of hyperactivity was broadly consistent across both sexes and age groups. Fifteen year old girls have consistently shown higher levels of hyperactivity difficulties than any other group (Figure 2.6).

Figure 2.6 - Trends in hyperactivity SDQ scores by sex and age (\% borderline or abnormal score)

Peer problems
2.26 Between 2006 and 2010, boys were more likely to have peer problems than girls. However, their scores have remained fairly static over time while girls' scores have worsened (particularly among 15 year olds girls). This has
meant that the gap has closed over time and by 2013 boys and girls had very similar scores (Figure 2.7).

Figure 2.7 - Trends in peer problems SDQ scores by sex and age (\% borderline or abnormal score)

## Pro-social score

2.27 In both age groups, girls were more likely to have normal pro-social scores than boys. This has been broadly consistent over time (Figure 2.8).

Figure 2.8 - Trends in pro-social SDQ scores by sex and age (\% normal score)

## WEMWBS

2.28 The WEMWBS scale was only added to SALSUS in 2010, so there is not yet long-term trend data. However, we can examine change between 2010 and 2013. In the WEMWBS scale, the lowest score possible score (indicating poor mental wellbeing) is 14 and the highest is 70 (indicating good mental wellbeing), so a higher average score for any particular group indicates higher mental wellbeing. The average ${ }^{2}$ WEMWBS score for all pupils decreased slightly between 2010 and 2013 from 50.0 to 48.7. This suggests that mental wellbeing decreased although not to a great extent.

[^1]2.29 With the exception of 15 year old girls, there has been little change in average WEMWBS scores between 2010 and 2013. Among the 15 year old girls, there was a small drop in mental wellbeing between 2010 and 2013 (Figure 2.9).

Figure 2.9 WEMWBS average score in 2010 and 2013 by age and sex

Full bases in Table A. 7 in Appendix A
Comparisons with other mental health and wellbeing indicators

## Existing findings from other sources

The Scottish Health Survey and the 'Scottish Health Behaviour in School-aged Children' (HBSC) Study confirm SALSUS findings:

- Mental health and wellbeing worsens with age
- Mental health and wellbeing is lower for 15 year old girls
2.30 In order to provide context to the findings, some of the mental health and wellbeing indicators from other surveys, namely the Scottish Health Survey (SHeS) (4) and the Health Behaviours in School-Aged Children (HBSC) study (5), will be discussed.
2.31 Tables 2.1-2.3 compare figures from the latest wave of the Scottish Health Survey (SHeS) with SALSUS 2013. Overall, mental wellbeing appeared to worsen as pupils aged. However, the figures were too small to show any significant differences (Table 2.1). The Scottish Health Survey also shows that boys have better mental health and wellbeing than girls (Table 2.3).

Table 2.1 Borderline or abnormal SDQ scores by age group

|  | SHeS 2014 |  |  |
| :--- | :---: | :---: | :---: |
|  | Age 4-6 | Age 7-9 | Age 10-12 |
| Overall | $11 \%$ | $14 \%$ | $17 \%$ |
| Emotion | $7 \%$ | $12 \%$ | $21 \%$ |
| Conduct | $18 \%$ | $17 \%$ | $22 \%$ |
| Hyperactivity | $21 \%$ | $21 \%$ | $19 \%$ |
| Peer problems | $17 \%$ | $19 \%$ | $23 \%$ |

|  | $\mathbf{1 3}$ years | $\mathbf{1 3}$ years | $\mathbf{1 5}$ years | $\mathbf{1 5}$ years |  |
| Average WEMWBS score | 50.2 | 51.3 | 45.1 | 50.2 |  |
| Bases | 7,249 | 7,494 | 7,427 | 7,482 |  |

Table 2.3 Average WEMWBS by age group and gender SHeS 2012/2013/2014

| SHeS 2012/2013/2014 combined |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: |
|  | Female <br> 13 <br> years | Male <br> 13 <br> years | Female <br> 15 <br> years | Male <br> Mears |
| Average WEMWBS Score | 50.7 | 53.0 | 49.0 | 51.3 |
| Bases | 115 | 136 | 135 | 123 |

2.32 With the exception of 13 year old girls, mental health and wellbeing reported by adolescents in the combined 2012/2013/2014 SHeS figures was higher on average than in SALSUS 2013 (Table 2.2 and 2.3).
2.33 HBSC also contains wellbeing measures, but not the SDQ or WEMWBS. The survey includes life satisfaction and self-confidence. A number of the key HBSC findings on wellbeing echo the SALSUS results:

- The prevalence of high life satisfaction falls with age, especially among girls ( $84 \%$ of 13 year old girls reported high life satisfaction, compared with $76 \%$ of 15 year old girls).
- Feeling confident 'always' was more common among boys than girls ( $19 \%$ of 13 year old boys and $15 \%$ of 15 year old boys, compared with $6 \%$ of 13 year old girls and $4 \%$ of 15 year old girls, respectively).
- Feeling confident 'always' has been decreasing gradually among both boys and girls.

## 3 Profile of mental health and wellbeing in 2013

## Key Findings

- Many factors showed an association with emotional and behavioural problems and, in most cases, an inverse relationship with mental health and wellbeing. However, there were two main areas that emerged as key to pupils' mental health and wellbeing:
o The number and nature of pupils' friendships - those who had fewer friends had poorer mental health and wellbeing e.g. 75\% of girls with no close friends had a borderline or abnormal overall SDQ score, as did those with older friends e.g. 17\% of pupils who had friends their own age had a borderline or abnormal conduct problems score compared with $41 \%$ of pupils with mostly older friends.
o The pupils' relationship with school - those that disliked school, felt pressured by school work, truanted on multiple occasions or had been excluded had poorer mental health and wellbeing than those that did not.
- Other factors that were associated with poorer mental health and wellbeing included:
o Below average maternal knowledge of activity
o Spending 6-7 nights out with friends per week
o Doing nothing, hanging out in the street or going to concerts gigs at least weekly.
- There were also variables that were linked to better mental health and wellbeing:
o Living with both parents
o Expecting to go to university after leaving school
o Belonging to a group or club
o Playing a sport, seeing friends or reading a book at least once a week.

## Geography

## Existing findings from other sources

- Previous research found that there was a relationship between population density and mental health - young people living in urban areas were more likely to report mental health problems. (6)
3.1 There was no clear difference in overall SDQ score by urban/rural classification. This was also the case for the individual scales that make up the Strengths and Difficulties questionnaire (Figure 3.1).

Figure 3.1 Individual SDQ scores by urban/rural classification (\% borderline or abnormal score) (2013)

3.2 In line with the SDQ measures of emotional and behavioural difficulties, mental wellbeing showed no relationship with urban/rural classification.
3.3 Figures C.1-C. 5 in Appendix C show the trends over time for the individual SDQ scales for each local authority ${ }^{3}$ (Tables C.1-C. 5 show the bases).
3.4 Pupils were most likely to have a borderline or abnormal scores on the overall SDQ score in Stirling and South Ayrshire ( $36 \%$ and $35 \%$ of pupils had a borderline or abnormal score, respectively). Pupils were least likely to have emotional or behavioural problems in Eilean Siar ( $24 \%$ of pupils had a borderline or abnormal score), East Renfrewshire (24\%) and Perth \& Kinross (21\%). The Scottish average borderline or abnormal score was (29\%) (See Table C. 6 in Appendix C for full results).

[^2]
## Family

## Existing findings from other sources

- Over half (55\%) of children with an emotional disorder had parents who had separated (7)
- The prevalence of mental disorders was higher in lone parent families than in two parent families and in reconstituted families, compared with families containing no step children (6)

Figure 3.8 Overall SDQ score by family status and sex (\% borderline or abnormal score) (2013)

Base: Full bases in Table D. 1 in Appendix D
3.5 Overall SDQ scores were associated with family status (Figure 3.8). Those living with both parents were least likely to have a borderline or abnormal score. Those living in single or step families had higher borderline or abnormal scores, while those that lived in 'other' (without either parent) family situations were the most likely to have borderline or abnormal scores. While this pattern was evident in both boys and girls, it was stronger among girls.

Figure 3.9 Individual SDQ scores by family status (\% borderline or abnormal score) (2013)

[^3]3.6 While those living with both parents had the lowest level of difficulties across all of the individual SDQ scales, there was some variation among the other groups (Figure 3.9). As with the overall SDQ measure, those living in 'other' family situations were most likely to have conduct, peer or pro-social problems. However, those living in step families were most likely to have emotional or hyperactivity problems.

Table 3.2 Average WEMWBS score by family status (2013)

| Family status | Average WEMWBS score | Bases |
| :--- | :--- | :--- |
| Both parents | 49.7 | 18771 |
| Single parent | 47.2 | 6760 |
| Step parent (and one parent) | 46.7 | 2539 |
| Other | 46.4 | 1217 |

3.7 Mental wellbeing showed a similar pattern to overall SDQ scores (Table 3.2). Those living with both parents had the highest average WEMWBS scores, followed by those in single parent families and step families. Those living in 'other' family situations had the poorest mental health and wellbeing.

Figure 3.10 Overall SDQ score by sex and mother's knowledge ${ }^{4}$ (2013)

3.8 Pupils whose mother knew an above average amount about their activities were less likely to have a borderline or abnormal SDQ score. This association was stronger among girls than boys (Figure 3.10).

[^4]Figure 3.11 Individual scores by mother's knowledge (\% borderline or abnormal scores) (2013)

3.9 The amount a pupil's mother knew about their activities was associated with all of the individual SDQ scales, although to differing extents. Mother's knowledge was most strongly associated with conduct problems and least strongly associated with peer problems (Figure 3.11).

Table 3.3 Average WEMWBS score by mother's knowledge (2013)

| Mother's knowledge of activities | Average WEMWBS score | Bases |
| :--- | :--- | :--- |
| Below average knowledge | 46.2 | 12524 |
| Average knowledge or above | 50.8 | 16412 |

3.10 Those whose mother knew an average or above average amount about their activities were more likely to have higher levels of mental health and wellbeing (Table 3.3).

## Friends

## Existing findings from other sources

- In England, a fifth ( $22 \%$ ) of children with emotional disorders found it more difficult than average to keep friends compared with only $5 \%$ of other children (8).
- Again, in England young people aged 11-16 with difficulty making and keeping friends increased their prevalence of developing emotional disorders such as anxiety and depression by $33 \%$ (8).
- A Finnish cohort study in 1981 found that children who had been bullied when they were 8 years old were more likely to have internalising and externalising problems and 3.5 times more likely to be referred for mental health services in later years (9).

Figure 3.12 Overall SDQ score by age of friends and sex (\% borderline or abnormal scores) (2013)

3.11 Pupils who said that their friends were the same age as them were the most likely to have normal overall SDQ scores, followed by those with friends of mixed ages and those with mostly younger friends (Figure 3.12). Those with mostly older friends were most likely to have borderline or abnormal scores. This pattern was the same among both sexes but was present in a greater degree among girls.

Figure 3.13 Individual SDQ scores by age of friends (\% borderline or abnormal scores) (2013)

[^5]3.12 The age of pupils' friends showed a similar pattern across most of the individuals SDQ scales. However, having younger friends was more closely related to both peer problems and pro-social problems (Figure 3.13).

Table 3.4 Average WEMWBS score by friends' age (2013)

| Age of friends | Average WEMWBS score | Bases |
| :--- | :--- | :--- |
| About the same age as me | 49.6 | 19031 |
| Younger than me | 48.2 | 435 |
| Mixed ages | 47.7 | 8099 |
| Older than me | 45.2 | 1140 |

3.13 Average WEMWBS score also showed a relationship with age of friends. As with overall SDQ score, mental wellbeing was higher among those who had friends that were the same age as them. Those with mostly older friends had the lowest average mental health and wellbeing (Table 3.3).

Figure 3.14 Overall SDQ score by number of friends and sex (2013)

3.14 Those who said that they had no close friends were much more likely to have a borderline or abnormal overall SDQ score. This was particularly the case among girls - three quarters of those with no close friends had a borderline or abnormal score (Figure 3.14).

Figure 3.15 Individual SDQ scores by number of friends (\% borderline or abnormal scores) (2013)

3.15 Although all of the individual SDQ scales were related to the number of friends a pupil had, unsurprisingly, the strongest association was with peer problems. Hyperactivity was the least strongly related to number of friends (Figure 3.15).

Table 3.5 Average WEMWBS score by number of friends (2013)

| Number of close friends | Average WEMWBS score | Bases |
| :--- | ---: | ---: |
| None | 39.7 | 441 |
| One | 43.8 | 922 |
| Two | 46.4 | 3604 |
| Three or more | 49.6 | 22771 |

3.16 As the number of friends a pupil had increased, so did the average WEMWBS score. Those with three or more friends had the highest average mental health and wellbeing (Table 3.5).

Figure 3.16 Overall SDQ score by number evenings spent with friends and sex (\% borderline or abnormal scores) (2013)

3.17 Spending a lot of time out with friends was associated with greater difficulties - pupils who spend 6-7 nights a week out with friends were most likely to have borderline or abnormal overall SDQ score. However, pupils who spent little or no time out with friends also were more likely to have higher borderline or abnormal scores. (Figure 3.16). In contrast, those who spent between 2 and 5 evenings with friends were the least likely to have a borderline or abnormal score.

Figure 3.17 Individual scores by number of evenings out with friends (\% borderline or abnormal scores) (2013)

I Base: Emotion (30480) Conduct (30512) Hyperactivity (30440) Peer problems (30463) Pro-social (30588)
Base. Emotion (30480) Conduct(30512) Hyperactivity (3044) Peer problems (30463) Pro-social (30588)
3.18 The individual SDQ scales did not all interact with evenings spent out with friends in the same way. While conduct problems and hyperactivity were associated most strongly with spending 6-7 nights out a week, peer problems, emotional problems and pro-social problems were most closely related to spending 0-1 nights out with friends a week (Figure 3.17).

Table 3.6 Average WEMWBS score by number of evenings spent with friends (2013)

| Number of evenings spent out with friends | Average WEMWBS score | Bases |
| :--- | ---: | ---: |
| $0-1$ evenings | 47.4 | 5508 |
| $2-3$ evenings | 49.2 | 10371 |
| $4-5$ evenings | 49.6 | 8392 |
| $6-7$ evenings | 48.2 | 4233 |

3.19 Spending little or no time out with friends was related to lower levels of mental wellbeing - the lowest average WEMWBS score was among those that spent 0-1 evenings out with friends per week (Table 3.6).

## School

## Existing findings from other sources

- Absenteeism and truancy rates were particularly high among those with socialised conduct disorder: 87\% of young people with a conduct disorder had been absent in the previous term (6).

Figure 3.18 Overall SDQ score by sex and by whether like school (\% borderline or abnormal score) (2013)

3.20 Whether or not a pupil liked school had a very clear relationship with overall SDQ score. Those that disliked school were far more likely to have a borderline or abnormal SDQ score. As with many of the other variables, this relationship was more evident among girls than boys (Figure 3.18). Girls who said that they did not like school at all were nearly five times more likely to have a borderline or abnormal score as those who said that they liked school a lot.

Figure 3.19 Individual scores by whether like school (\% borderline or abnormal scores) (2013)

3.21 Whether or not a pupil liked school was strongly associated with all of the individual SDQ scales, particularly conduct problems (Figure 3.19).

Table 3.7 Average WEMWBS score by whether like school (2013)

| Whether like school | Average WEMWBS score | Bases |
| :--- | ---: | ---: |
| I like it a lot | 54.6 | 5537 |
| I like it a bit | 49.8 | 14857 |
| I don't like it very much | 44.8 | 5451 |
| I don't like it at all | 39.8 | 2697 |

3.22 In line with the emotional and behaviour difficulties scores, mental health and wellbeing was linked to liking school - pupils that disliked school the most had the lowest average WEMWBS score (Table 3.7).

Figure 3.20 Overall SDQ score by sex and by school pressure (\% borderline or abnormal score) (2013)

Full bases in Table D. 7 in Appendix D
$\qquad$
3.23 Pupils who felt pressured by school work a lot of the time were much more likely to report borderline or abnormal overall SDQ scores (Figure 3.20). Girls who felt pressured a lot of the time were three times more likely to have a borderline or abnormal score than those who never felt pressure.

Figure 3.21 Individual scores by school pressure (\% borderline or abnormal scores) (2013)

I Base: Emotion (30792) Conduct (30828) Hyperactivity (30755) Peer problems (30778) Pro-social (30901)
3.24 The individual SDQ scales were also related to feeling pressure from schoolwork, with the exception of the pro-social scale. The relationship was most evident in relation to emotional problems - those that felt a lot of pressure were more than four times more likely to have a borderline or abnormal score than those that never feel pressure (Figure 3.21).

Table 3.8 Average WEMWBS score by school pressure (2013)

| Whether feel pressured by school work | Average WEMWBS score | Bases |
| :--- | ---: | ---: | ---: |
| Never | 52.7 | 4444 |
| Sometimes | 50.2 | 16107 |
| A lot of the time | 44.2 | 8126 |

3.25 As with the SDQ scales, mental wellbeing was related to feeling pressure from schoolwork. Those that felt pressure a lot of the time had the lowest average WEMWBS scores (Table 3.8).

Figure 3.22 Overall SDQ score by sex and by number of times truanted (2013) (\% borderline or abnormal score)

3.26 In line with the other school related variables, truanting was associated with overall difficulties. The more frequently a pupil truanted, the more likely they were to have a borderline or abnormal overall SDQ score (Figure 3.22).

Figure 3.23 Individual SDQ scores by number of times truanted (\% borderline or abnormal scores) (2013)

3.27 Truanting was most strongly correlated with conduct problems. Those that had truanted were four times as likely to have a borderline or abnormal score as those who had never truanted. However, all of the individual SDQ scales had a relationship with truanting (Figure 3.23).

Table 3.9 Average WEMWBS score by truanting (2013)

| Number of times truanted | Average WEMWBS score | Bases |
| :--- | ---: | ---: |
| None | 50.1 | 19147 |
| $1-3$ times | 47.5 | 6642 |
| $4-10$ times | 44.8 | 1830 |
| More than 10 times | 41.8 | 955 |

3.28 Lower WEMWBS scores, suggesting lower mental wellbeing, were evident among those that truanted more frequently (Table 3.9).

Figure 3.24 Overall SDQ score by sex and by exclusion (2013)

3.29 Pupils who had even been excluded from school were more likely to have a borderline or abnormal overall SDQ score (Figure 3.24).

Figure 3.25 Individual SDQ scores by whether ever excluded (\% borderline or abnormal scores) (2013)

3.30 Pupils who had been excluded were more likely to have borderline or abnormal scores on every individual SDQ score. As with truanting, the association was strongest between exclusion and conduct problems (Figure 3.25).

Table 3.10 Average WEMWBS score by exclusion (2013)

| Ever excluded | Average WEMWBS score | Bases |
| :--- | ---: | ---: |
| Yes | 46.1 | 2490 |
| No | 49.1 | 26000 |

3.31 Mental wellbeing was associated with exclusion - those that had been excluded had a lower average WEMWBS score than those that had not (Table 3.10).
Figure 3.26 Overall SDQ score by sex and by Free School Meal (FSM) entitlement ${ }^{5}$ (2013)

3.32 Those that reported that they were entitled to receive free school meals ${ }^{6}$ were more likely to have a borderline or abnormal overall SDQ score (Figure 3.26).

Figure 3.27 Individual SDQ scores by Free School Meal (FSM) entitlement (\% borderline or abnormal scores) (2013)

3.33 With the exception of the pro-social scale, each of the individual SDQ measures was related to free school meal entitlement. As before, entitlement to free school meals was associated with higher proportions of borderline or abnormal scores (Figure 3.27).
${ }^{5}$ Free school meals are provided to those whose parents receive benefits or incomes fall below a certain threshold. As such, free school meal entitlement is often used as a proxy for the level of deprivation of pupils' families.
${ }^{6}$ Figures on free school meals entitlement were based on pupils' survey responses and not official records. Official records show 41,744 pupils ( $15 \%$ of pupils) were registered for free meals in Scottish secondary schools in 2013. In SALSUS 2013, 12\% of pupils said they received free school meals - which is very similar. http://www.gov.scot/Resource/0047/00479422.pdf

Table 3.11 Average WEMWBS score by Free School Meal (FSM) entitlement (2013)

| Free School Meal entitlement | Average WEMWBS score | Bases |
| :--- | ---: | ---: | ---: |
| Yes | 47.2 | 3229 |
| No | 49.1 | 23172 |

3.34 Mental wellbeing was lower among those who were in receipt of free school meals (Table 3.11).

Figure 3.28 Overall SDQ score by expectations after school and sex ${ }^{7}$ (\% borderline or abnormal score) (2013)

I Full bases in Table D. 11 in Appendix D
3.35 With regard to post-school expectations, those who thought they would go to university were less likely to have borderline or abnormal scores than all other groups (Figure 3.28).

Figure 3.29 Individual SDQ scores by expectations after school (\% borderline or abnormal scores) (2013)

3.36 While expecting to go to university after school was associated with lower levels of borderline or abnormal scores among four of the five individual SDQ scales, it was not closely related to emotional problems (Figure 3.29).

[^6]Table 3.12 Average WEMWBS score by expectations after school (2013)

| Expectations after school | Average WEMWBS score | Bases |
| :--- | ---: | ---: |
| University | 49.9 | 16992 |
| FE college | 46.6 | 4788 |
| Apprenticeship | 50.5 | 1328 |
| Working | 47.9 | 2305 |
| Other | 46.4 | 4406 |

3.37 Those that thought they would complete an apprenticeship after school had the highest average WEMWBS score, closely followed by those who thought that they would go to university (Table 3.12).

## Leisure activities

## Existing findings from other sources

- Participation in leisure activities had a significant impact on young people's mental health. However this depended on the type of leisure activity: active leisure was associated with better mental health while sedentary leisure was associated with poorer mental health (10).

Figure 3.30 Regular leisure activities and overall SDQ score (2013)

3.38 Among boys and girls, playing sport and seeing friends at least weekly were associated with lower proportions of borderline or abnormal overall SDQ scores. In contrast, doing nothing, hanging out in the street and going to a concert or gig at least once a week were linked to higher proportions of borderline or abnormal overall SDQ scores (Figure 3.30).

Figure 3.31 Regular leisure activities and emotional problems score (2013)

3.39 As with the overall SDQ score, emotional problems were related to doing nothing (in boys and girls), hanging out in the street (in girls) and going to a concert or gig (in boys) at least weekly. However, among girls they were also associated with social networking and listening to music on a weekly basis. Playing sport and seeing friends were related to lower levels of emotional problems (Figure 3.31).

Figure 3.32 Regular leisure activities and conduct problems score (2013)

3.40 Reading books at least weekly was associated with lower levels of conduct problems in boys and girls, whereas higher levels were associated with hanging out in the street, going to a concert or gig and doing nothing at least weekly (Figure 3.32).

Figure 3.33 Regular leisure activities and hyperactivity problems score (2013)

3.41 Going to church, temple or mosque and reading books on a weekly basis were associated with lower levels of hyperactivity among boys and girls. In contrast, hanging out in the street, doing nothing and using social networking were linked to higher levels of hyperactivity in both sexes (Figure 3.33).

Figure 3.34 Regular leisure activities and peer problems score (2013)

3.42 Seeing friends, playing sport and going to a friend's house at least weekly were all associated with lower proportions reporting borderline or abnormal peer problems scores. Unlike a number of the other individual SDQ scales, social networking was also linked to lower levels of peer problems. As with the other individual SDQ scales, doing nothing and going to a gig or concert at least weekly were related to higher levels of peer problems (Figure 3.34).

Figure 3.35 Regular leisure activities and pro-social score (2013)

3.43 Playing sport, doing a hobby, and reading books at least weekly were associated with pro-social behaviours among both sexes. Doing nothing and going to a gig or concert at least weekly were associated with lower levels of pro-social behaviour (Figure 3.35).

Table 3.13 Average WEMWBS scores by frequency of leisure activities (2013)

| Leisure activities | At least once a week | Less often |
| :--- | ---: | ---: |
| Do nothing | 44.9 | 50.0 |
| Go to concerts/gigs | 47.3 | 49.0 |
| Hanging out in the street | 47.8 | 49.4 |
| Do a hobby | 47.9 | 49.5 |
| Social networking | 48.6 | 50.0 |
| Listen to music | 48.9 | 49.3 |
| Watch DVDs | 48.9 | 48.4 |
| Go to shops | 49.1 | 48.3 |
| Go to cinema | 49.1 | 48.7 |
| Go to friends house | 49.1 | 48.2 |
| Read magazines | 49.2 | 48.7 |
| See friends | 49.4 | 46.5 |
| Play computer games | 49.5 | 47.7 |
| Volunteer | 49.5 | 48.7 |
| Read books | 49.6 | 48.2 |
| Go to church | 50.1 | 48.6 |
| Play sports | 50.5 | 45.8 |
| Watch sports | 50.6 | 48.1 |

3.44 Watching and playing sport at least weekly were most strongly related to higher levels of mental health and wellbeing, while doing nothing, going to concerts and gigs and hanging out in the street at least weekly were the strongest negatively associated activity (Table 3.13).

Figure 3.36 Group/club membership by overall SDQ score and sex (2013)

I Full bases in Appendix E
3.45 Those who had attended a group or club (e.g. youth groups, drama clubs, sports clubs or computer clubs etc.) were less likely to have a borderline or abnormal overall SDQ score (Figure 3.36).

Figure 3.37 Individual SDQ scores by group/club membership (\% borderline or abnormal score) (2013)

3.46 As with overall SDQ score, the individual scales all showed a relationship with group/club membership. For each scale, group membership was associated with a lower proportion of pupils reporting borderline or abnormal scores (Figure 3.37).

Table 3.14 Average WEMWBS score by club membership (2013)

| Member of a club or group? | Average WEMWBS score | Bases |
| :--- | ---: | ---: | ---: |
| Yes | 49.6 | 23474 |
| No | 45.5 | 5348 |

3.47 In line with the correlation between group membership and difficulties scores, group membership was also associated with higher levels of mental health and wellbeing (Table 3.14).

## 4 Equalities and mental health and wellbeing in 2013

## Key Findings

- Girls were more likely than boys to have borderline or abnormal scores for the overall SDQ scale, emotional problems and hyperactivity. However, boys were more likely than girls to have problems with conduct, peers or pro-social behaviour.
- Emotional and behavioural problems appeared to increase, while mental health and wellbeing decreased as pupils moved further into adolescence.
- Pupils who reported that they had a limiting illness or disability tended to suffer from poorer mental health and wellbeing as well as poorer physical health.
- Pupils who had a mixed or multiple ethnicity were more likely to suffer from poor mental health and wellbeing than those from other ethnicities.
- Higher levels of deprivation were correlated with poorer mental health and wellbeing. Both Scottish Index of Multiple Deprivation (SIMD) and perceived family affluence, showed a relationship with mental health and wellbeing. However, perceived family affluence had a stronger association than the geography based measure of deprivation (SIMD).

## Existing findings from other sources

- Rates of mental health problems among children increase as they reach adolescence. Disorders affect $10 \%$ of boys aged $5-10$, rising to $13 \%$ of boys aged 11 15 , and $6 \%$ of girls aged $5-10$, rising to $10 \%$ of girls aged 11-15. (6)
- Prevalence of depressed mood or anxiety was 2.5 times higher among young people aged 10 to 15 years with low socioeconomic status than among youths with a higher socioeconomic status (11).
- The parents of children with an emotional disorder were more than four times as likely as other parents to say that their child's general health was fair or bad ( 23 per cent compared with 5 per cent) (6).
- In terms of young people aged 5-16 years, $9 \%$ of children from Black backgrounds, $8 \%$ of children from Pakistani and Bangladeshi backgrounds, and 3\% of children from Indian backgrounds had a mental disorder compared to $10 \%$ of children from White backgrounds (12).

## Equalities questions in SALSUS

4.1 The equalities variables considered in this report are sex, age, illness/disability, ethnicity and deprivation (SIMD and perceived family affluence).

## Equalities variables in SALSUS 2013

4.2 Figure 4.1 shows the breakdown of the sample for each of the equalities variables included in the SALSUS survey.

Figure 4.1 - Pupil breakdown of equalities variables, 2013

4.3 It should be borne in mind that using SIMD means that we are looking at an area based measure to identify deprivation in individuals. Many people who are materially disadvantaged as individuals live in areas that are not particularly deprived in terms of SIMD; equally, many people living in deprived areas (as identified by SIMD) may not be particularly disadvantaged. For that reason, it is also important to look at family level measures of deprivation (perceived affluence).
4.4 In 2013, 37\% of pupils did not supply a postcode - either because they did not know it or did not want to write it in. Missing postcodes were imputed by sorting the data by class within schools. If a postcode was missing, the postcode of another randomly selected pupil from the same class was used.
4.5 The figures suggest that those who did not provide a postcode were more likely to be those living in areas of deprivation (see Table 4.1). Imputing the postcodes improved this but those living in the most deprived areas were still underrepresented. The data was weighted to account for these differences.

Table 4.1 SALSUS 2013 - SIMD by postcode imputation ${ }^{8}$

|  | SIMD before <br> postcode <br> imputation and <br> checking | SIMD after <br> postcode <br> imputation and <br> checking | SIMD after <br> weighting <br> applied | Population <br> estimates for 13 <br> and 15 year olds <br> 2013 |
| :--- | ---: | ---: | ---: | ---: |
| SIMD 1 - most <br> deprived | $16 \%$ | $17 \%$ | $18 \%$ | $20 \%$ |
| SIMD 2 | $17 \%$ | $18 \%$ | $19 \%$ | $18 \%$ |
| SIMD 3 | $20 \%$ | $20 \%$ | $19 \%$ | $19 \%$ |
| SIMD 4 | $24 \%$ | $24 \%$ | $24 \%$ | $21 \%$ |
| SIMD 5 - least <br> deprived | $22 \%$ | $21 \%$ | $21 \%$ | $21 \%$ |
| Bases | 33,685 | 33,685 | 33,685 | 115,915 |

## Equalities variables by mental health and wellbeing

4.6 Overall, girls were more likely than boys to have a borderline or abnormal SDQ score. While girls were more likely to have borderline or abnormal scores for emotional problems and hyper activity, boys were more likely to have borderline or abnormal scores on the conduct, hyperactivity and prosocial scales (Figure 4.2).

[^7]Figure 4.2 SDQ scales, including overall score, by sex (\% borderline or abnormal score) (2013)

I Base: Overall SDQ (30946) Emotion (31033) Conduct (31069) Hyperactivity (30995) Peer problems I (31018) Pro-social (31154)
4.7 Boys also had a higher average WEMWBS score than girls indicating higher levels of mental wellbeing (Table 4.2).

Table 4.2 Average WEMWBS score by sex

| Sex | Average WEMWBS score | Base |
| :--- | ---: | ---: |
| Male | 50.7 | 14976 |
| Female | 46.8 | 15017 |

4.8 A higher proportion of 15 year olds had borderline or abnormal scores on the overall SDQ, emotions, hyperactivity and pro-social scales than 13 year olds. There was no difference between the year groups on the conduct and peer problems scales (Figure 4.3).

Figure 4.3 SDQ scales, including overall score, by age (\% borderline or abnormal score) (2013)

$4.9 \quad 13$ year olds had a higher average WEMWBS score than 15 year olds suggesting that they are more likely to have better mental wellbeing (Table 4.3).

Table 4.3 Average WEMWBS score by age

| Age | Average WEMWBS score | Base |
| :--- | ---: | ---: |
| S2 | 50.0 | 15107 |
| S4 | 47.6 | 14936 |

4.10 Having a limiting illness or disability was associated with higher borderline or abnormal scores on all of the SDQ scales, with the exception of the prosocial scale, but including the overall difficulties score (Figure 4.4).

Figure 4.4 SDQ scales, including overall score, by whether have limiting illness or disability (\% borderline or abnormal score) (2013)

4.11 Those with a limiting illness or disability had lower levels of mental health and wellbeing than those who did not (Table 4.4).

Table 4.4 Average WEMWBS score by illness or disability

| Limiting illness or disability | Average WEMWBS score | Base |
| :--- | ---: | ---: |
| Yes | 45.0 | 4112 |
| No | 49.3 | 25563 |

4.12 Pupils who had a mixed or multiple ethnicity were most likely to have a borderline or abnormal score on every SDQ scale except for hyperactivity. Asian pupils were least likely to have emotional and behavioural difficulties (Figure 4.5).

Figure 4.5 SDQ scores by ethnicity (\% borderline or abnormal score) (2013)

4.13 In line with the SDQ figures, it was pupils with a mixed or multiple ethnicity who had the lowest average mental health and wellbeing score (Table 4.5).

Table 4.5 Average WEMWBS score by ethnicity

| Ethnicity | Average WEMWBS score | Base |
| :--- | ---: | ---: |
| White | 48.8 | 27293 |
| Asian | 49.3 | 777 |
| Black | 49.7 | 177 |
| Mixed | 47.1 | 945 |

4.14 Pupils who lived in the most deprived areas were most likely to have a borderline or abnormal score on every SDQ measure except emotional problems which did not show such a clear cut relationship with SIMD (Figure 4.6).

Figure 4.6 SDQ scales by SIMD (\% borderline or abnormal score) (2013)

[^8]I Pro-social (31211)
4.15 Average mental wellbeing increased as deprivation level decreased. However, the relationship was not that strong (Table 4.6).

Table 4.6 Average WEMWBS score by SIMD

| SIMD | Average WEMWBS score | Base |
| :--- | ---: | ---: |
| 1 - Most deprived quintile | 48.0 | 4789 |
| 2 | 48.5 | 5264 |
| 3 | 48.2 | 6101 |
| 4 | 49.2 | 7312 |
| 5 - Least deprived quintile | 49.5 | 6577 |

4.16 Perceived family affluence had a stronger relationship with emotional and behavioural difficulties than SIMD. Pupils who thought that their family was not well off were more likely to have borderline or abnormal scores on each of the individual SDQ measures with the exception of the pro-social scale (Figure 4.7).

Figure 4.7 SDQ scales by perceived affluence (\% borderline or abnormal score) (2013)

4.17 Pupils who thought that their family was either very or quite well off had higher levels of mental health and wellbeing than those who thought that their family was not or not at all well off (Table 4.7).

Table 4.7 Average WEMWBS score by perceived affluence

| Perceived affluence | Average WEMWBS score | Base |
| :--- | ---: | ---: |
| Very well off | 51.5 | 4395 |
| Quite well off | 50.1 | 11322 |
| Average | 47.3 | 11956 |
| Not well off | 43.9 | 1161 |
| Not at all well off | 42.3 | 377 |

## 5 Predictors of mental health and wellbeing

## Key findings

There is very little difference in the predictors of mental health and wellbeing among girls and boys.

Views on school and school-work and the number and nature of friendships are the key drivers of mental health and wellbeing among girls and boys.

- Feeling pressured by schoolwork, not liking school, frequent truanting, and exclusion from school all had a large impact on the likelihood to have a borderline or abnormal overall SDQ score.
- Number of close friends, evenings spent with friends, and the ages of friends all had an impact on overall SDQ scores.

A range of other factors are associated with mental health and wellbeing such as family affluence, parental knowledge and some leisure activities. However, these are not as closely associated with mental health as views on school and friendship patterns.

Once all other factors are included, age does not have a large impact on mental health and wellbeing.
5.1 Logistic regression is used to predict an outcome using several predictor variables. In this report, logistic regression was used to predict borderline or abnormal scores on the components of the Strengths and Difficulties questionnaire and the overall SDQ score. The data used was limited to 2013 and the models were run separately for girls and boys ${ }^{10}$.
5.2 The main benefit of using logistic regression in this context is to clearly distinguish the different effects of the various factors. By including in the logistic regression models, for example, the Scottish Index of Multiple Deprivation (SIMD) and perceptions of family affluence, it is possible to separate the effect of each of these. This means that any significant difference by any factor is independent of any other factors (i.e. whether area deprivation is a significant factor that is separate from family affluence).
5.3 Two sets of six logistic regression models were run separately for boys and girls: borderline or abnormal versus normal scores on the five components of SDQ and the overall SDQ score. These were run separately because of the sizeable differences in the profile of mental health and wellbeing scores for boys and girls.

[^9]5.4 The potential factors included in each of the logistic regressions were those analysed across the six themes covered earlier in this report: geography, family, friends, school, leisure activities and equalities variables. The factors included are summarised in Table 5.1.
5.5 All models were run three times: with all variables included, using forward conditional selection and backward conditional selection. Forward and backward conditional selections only retain variables in the model that have some explanatory power. Overall, almost all explanatory variables had an impact in at least one of the models. The full results of every model (with the non-significant factors included) are shown in Appendix F.

Table 5.1 - Factors included in each logistic regression

| Geography | Family | Friends | School | Leisure activities | Equalities |
| :---: | :---: | :---: | :---: | :---: | :---: |
| - Rurality | - Family status <br> - Maternal knowledge <br> - Paternal knowledge | - Age of friends <br> - Number of close friends <br> - Number of evening spent with friends | - Attitude to school <br> - Whether pressured by school work <br> - Truanting <br> - Exclusion <br> - Expectations after school | - Group/club membership <br> - Weekly participation in various leisure activities | - Sex <br> - Age <br> - Perceived family affluence <br> - Scottish Index of Multiple Deprivation (SIMD) <br> - Free School Meal entitlement |

## What the models show

## Key drivers of mental health and wellbeing among girls

5.6 Figure 5.1 highlights the key drivers of borderline or abnormal mental health and wellbeing scores among girls. The detailed regression results can be found in Tables 1a and 1b in Appendix F).

Figure 5.1 Summary of key drivers of borderline or abnormal mental health among girls in $2013^{11}$

|  | SIGNIFICANT FACTOR? |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

5.7 Feelings towards school and schoolwork were closely linked to mental health and wellbeing among girls. Feeling pressured by schoolwork, not liking school, frequent truanting, and exclusion from school all had a large impact on likelihood to have a borderline or abnormal overall SDQ score. All of these, with the exception of exclusion from school, also had a significant impact on all five components of the SDQ score separately. Being excluded from school was linked to the conduct, hyperactivity, peer components but not to the emotion or pro-social components of SDQ.
5.8 Of all factors included in the model, being pressured by schoolwork was the strongest predictor of being borderline or abnormal on the SDQ score overall, and significant for all the components individually. It is noteworthy that not being pressured by schoolwork among girls meant that they were more likely to score as borderline or abnormal on the pro-social scale. For the other four components, the relationship is in the other direction pressure of schoolwork leads to a higher likelihood of borderline or abnormal scores.
5.9 After feelings towards school and school work were controlled for, expectations of post-school transitions were also related to mental health

[^10]and wellbeing. Those that thought that they would do an apprenticeship, go into Further Education, or start working, were more likely than those who thought they would go to university to score as borderline or abnormal on the SDQ overall. Expectations of doing an apprenticeship was also linked to borderline or abnormal scores on conduct and peer problems.
5.10 Relationships with friends were also closely linked to mental health and wellbeing among girls. Having more close friends was strongly correlated to reduced emotional problems, peer problems and borderline or abnormal SDQ score overall. Number of friends, however, was not a driver of conduct, hyper-activity or the pro-social components of SDQ among girls.
5.11 Ages of friends were linked to all components of mental health and wellbeing. Those who reported that their friends were the same age as them or that their friends were of mixed ages were more likely to have good mental health and wellbeing scores across all five components. Those who said that their friends were older than them were more likely to score as borderline or abnormal.
5.12 The relationship between evenings spent with friends and the SDQ mental health and wellbeing components was more complex. Overall, spending evenings with friends was linked to positive mental health and wellbeing. It had a positive impact on the emotion, peer, and pro-social components of SDQ. However, in terms of conduct and hyper-activity, spending evenings with friends was correlated to poorer scores.
5.13 Among girls, perceptions of family affluence were related to SDQ scores, with lower affluence being associated with a higher likelihood of borderline or abnormal scores on SDQ overall. The impact of family affluence differs across the different components of SDQ. Scores for emotion and hyperactivity were closely associated with views on family affluence, and scores for conduct and peer problems were also correlated but to a lesser extent.
5.14 The relationship between affluence and mental health and wellbeing is not straightforward. While views on family affluence were a clear driver on mental health and wellbeing, once this factor is included in the modelling, entitlement to Free School Meals and area deprivation were not driving patterns of mental health and wellbeing among girls as much as other factors.
5.15 Similarly, the relationship between age and mental health and wellbeing is not straightforward. Poor mental health and wellbeing is more prevalent among S4 than S2 girls. However, age did not come out as a significant factor in the modelling of the overall SDQ score. This suggests that age by itself is not a key driver of mental health and wellbeing. Instead, it reflects the prevalence of other drivers changing as pupils get older. Most notably, S4 girls are more likely than S2 girls to feel pressurised by schoolwork and to not like school.
5.16 A number of leisure activities were included in the logistic regression model. Generally, these were less closely associated with mental health and wellbeing among girls than their views on school and schoolwork and their relationship with friends. Hanging around the streets was linked with higher borderline or abnormal SDQ scores overall, and also closely linked with scores on the conduct component. Using social networking sites was related to an increased likelihood of borderline or abnormal scores on emotion and hyperactivity, but a decreased likelihood of such scores on the peer problems scale. Doing voluntary work was related to an increased likelihood of borderline or abnormal scores on emotion and peer problems, but a decreased likelihood of pro-social borderline or abnormal scores. Full details of these are provided in the Appendix F.

## Key drivers of mental health and wellbeing among boys

5.17 Although the increase in mental health and wellbeing issues among girls over time has been much more considerable than among boys, the factors that had the strongest impact on girls also had the largest impact on boys' mental health and wellbeing, with views on school and schoolwork and friendships having the strongest impact.

Figure 5.2 Summary of key drivers of borderline or abnormal mental health and wellbeing among boys in 2013

5.18 Figure 5.2 highlights the factors that had the biggest impact on the different SDQ components of mental health and wellbeing among boys (detailed regression results can be found in Appendix F).
5.19 Feelings towards school and schoolwork were closely linked to mental health and wellbeing among boys. Like girls, feeling pressured by schoolwork, not liking school, frequent truanting, and exclusion from school all had a large impact on likelihood to be borderline or abnormal on the overall SDQ score. All of these, with the exception of truanting from school, also had a significant impact on all five components of the SDQ score separately. Truanting was linked to all components of SDQ with the exception of peer problems.
5.20 As with girls, of all factors included in the model, being pressured by schoolwork was the strongest predictor of being borderline or abnormal on the SDQ score overall among boys and significant for all the components individually. Again, like among girls, not being pressured by schoolwork among boys meant that they were more likely to score as borderline or abnormal on the pro-social scale. For the other four components, the relationship is in the other direction - pressure of schoolwork led to a higher likelihood of borderline or abnormal scores.
5.21 Among boys, expectations post-school were also related to mental health and wellbeing. Those that thought that they would do an apprenticeship, go into Further Education, or start working, were more likely than those who thought they would go to university to score as borderline or abnormal on the SDQ overall. Expectations of going into work or FE, compared to going to university were linked to borderline or abnormal scores on conduct, hyper-activity, peer problems, and the pro-social component. In contrast, expectations of undertaking an apprenticeship were related to increased borderline or abnormal scores on conduct and hyperactivity, but not in relation to peer problems or the pro-social component.
5.22 Among boys, relationships with friends were also closely linked to mental health and wellbeing. Having more close friends was strongly correlated to reduced emotional problems, peer problems and borderline or abnormal SDQ score overall. Number of friends, however, was not a driver of conduct, hyper-activity or the pro-social components of SDQ. This is the same as for girls.
5.23 Ages of friends were linked to all components of mental health and wellbeing. Those who reported that their friends were the same age as them were more likely to have good scores across all five components, and those who said that their friends were of mixed ages were more likely to have good scores across on emotion, conduct and peer problems. Those who said that their friends were older than them were more likely to score as borderline or abnormal. This is broadly the same pattern as girls.
5.24 Overall, as with girls, spending evenings with friends was linked to positive mental health and wellbeing among boys. It has a positive impact on the peer, and pro-social components of SDQ. However, in terms of conduct, spending evenings with friends was correlated to poorer scores.
5.25 Among boys, perceptions of family affluence were also related to SDQ scores, with lower affluence associated with a higher likelihood of borderline or abnormal scores on SDQ overall. Again, the impact of family affluence differs across the different components of SDQ. Scores for emotion, hyperactivity, and peer problems were correlated with views on family affluence. Among boys, scores for pro-social were inversely correlated to views on family affluence - those who say their family was well-off were more likely to score borderline or abnormal on the pro-social component.
5.26 Again, once views on family affluence were controlled for, entitlement to Free School Meals and area deprivation were not strong drivers of mental health and wellbeing among boys.
5.27 As with girls, leisure activities were included in the logistic regression model. While hanging around the streets was linked with higher borderline or abnormal SDQ score overall, doing voluntary work was not. Doing voluntary work was, however, related to conduct and peer problems and was linked to decreased likelihood of pro-social borderline or abnormal scores. This is the same pattern as was seen among girls.
5.28 However, unlike girls, using social networking sites was not linked to higher borderline or abnormal SDQ score overall among boys. Full details of these are provided in the logistic regression given in Appendix F.
5.29 Overall, the analysis suggests that while the prevalence of mental health and wellbeing problems has diverged between girls and boys in recent years, the main drivers have not. Pressure of schoolwork and the nature and number of friendships are central to mental health and wellbeing.

## 6 Conclusions

- In the last three years, there has been a marked change in mental health and wellbeing among pupils. While some aspects have improved (conduct problems, pro-social behaviour) or remained largely the same over time (hyperactivity, mental wellbeing), others have worsened (emotional problems and peer problems).
- One of the starkest changes is the extent to which mental health and wellbeing has changed among 15 year old girls, particularly in terms of their emotional wellbeing. In 2010, 28\% of 15 year olds girls had a borderline or abnormal emotional problems score. This increased to $41 \%$ in 2013.
- Among those components of mental health and wellbeing that have deteriorated, the main change has been between 2010 and 2013, rather than a gradual effect over time.
- Different aspects of mental health and wellbeing affected girls and boys differently - girls were more likely to have problems with emotion or hyperactivity, whereas boys were more likely to have problems with conduct, peers or pro-social behaviour.
- When it comes to mental health and wellbeing, the two most closely aligned factors are pupils' relationships with friends and their experience of school. This was confirmed by the logistic regression analysis.
- The number and nature of a pupil's friendships had the strongest links to mental health and wellbeing - poorer mental health and wellbeing was associated with having fewer friends and having mostly older friends.
- Engagement with school was key to good mental health and wellbeing - those that disliked school, felt pressured by the amount of work they had, truanted on multiple occasions or had been excluded were all more likely to have borderline or abnormal SDQ scores and lower mental health and wellbeing.
- Physical wellbeing was linked to mental health and wellbeing - those who had a limiting illness or disability reported poorer mental health and wellbeing than those that did not - particularly in relation to emotional problems.
- A number of activities appeared to have a protective effect against poor mental health and wellbeing (although causal links are likely to be complex). Expecting to go to university, belonging to a group or club and seeing friends, doing a hobby, reading books or playing a sport at least weekly were associated with better mental health and wellbeing. For girls, in particular, playing sport on a weekly basis was strongly related to lower levels of emotional and behavioural problems.

## Appendix D - Chapter 3 bases

Table D.1 - Bases for figure 3.8 Overall SDQ score by family status and sex (\% borderline or abnormal score) (2013)

|  | Single parent | Step parent (and <br> one parent) | Both parents | Other |
| ---: | ---: | ---: | ---: | ---: |
| Male | 3440 | 1101 | 9654 | 685 |
| Female | 3498 | 1502 | 9802 | 578 |

Table D. 2 - Bases for figure 3.10 Overall SDQ score by mother's knowledge and sex (2013)

|  | Below median knowledge | Median knowledge or above |
| :---: | ---: | ---: |
| Male | 6091 | 8591 |
| Female | 6718 | 8552 |

Table D. 3 - Bases for figure 3.12 Overall SDQ score by age of friends and sex (\% borderline or abnormal scores) (2013)

|  |  |  |  |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
|  | Older than me the same | Younger than me |  | age as me | Mixed ages |
| Male | 628 | 298 | 10004 | 4119 |  |
| Female | 596 | 180 | 10237 | 4527 |  |

Table D. 4 - Bases for figure 3.14 Overall SDQ score by number of friends and sex (2013)

| Male | None | One or more |
| ---: | ---: | ---: |
| Female | 282 | 13962 |

Table D. 5 - Bases for figure 3.16 Overall SDQ score by number evenings spent with friends and sex (\% borderline or abnormal scores) (2013)

|  | $0-1$ evenings | $2-3$ evenings | $4-5$ evenings | $6-7$ evenings |
| ---: | ---: | ---: | ---: | ---: |
| Male | 2816 | 5250 | 4519 | 2334 |
| Female | 1944 | 4120 | 2934 | 1271 |

Table D. 6 - Bases for figure 3.18 Overall SDQ score by whether like school and sex (\% borderline or abnormal score) (2013)

|  | I like it a lot | I like it a bit | I don't like it very <br> much |  |  | I don't like it at all |
| ---: | ---: | ---: | ---: | ---: | :---: | :---: |
| Male | 3012 | 8094 | 2614 | 1312 |  |  |
| Female | 2490 | 5751 | 1609 | 462 |  |  |

Table D. 7 - Bases for figure 3.20 Overall SDQ score by school pressure and sex (\% borderline or abnormal score) (2013)

|  | Never | Sometimes | A lot of the time |
| :---: | ---: | ---: | ---: |
| Male | 2741 | 9158 | 3208 |
| Female | 1742 | 5996 | 2609 |

Table D. 8 - Bases for figure 3.22 Overall SDQ score by number of times truanted and sex (\% borderline or abnormal score) (2013)

| None | 1-3 times | $4-10$ times | More than 10 <br> times |  |
| :---: | :---: | ---: | ---: | ---: |
| Male | 9967 | 3607 | 946 | 511 |
| Female | 7934 | 1873 | 387 | 131 |

Table D. 9 - Bases for figure 3.24 Overall SDQ score by exclusion and sex (2013)

| Male | No | Yes |
| :---: | :---: | ---: |
| Female | 13384 | 1605 |

Table D. 10 - Bases for figure 3.26 Overall SDQ score by Free School Meal (FSM) entitlement and sex (2013)

|  | Yes | No |
| ---: | ---: | ---: |
| Male | 1660 | 12156 |
| Female | 1036 | 8545 |

Table D. 11 - Bases for figure 3.22 Overall SDQ score by number of times truanted and sex (\% borderline or abnormal score) (2013)

|  | University | FE college | Apprenticeship | Working | Other |
| ---: | ---: | ---: | ---: | ---: | ---: |
| Male | 7557 | 2108 | 1207 | 1600 | 2683 |
| Female | 7276 | 1550 | 68 | 436 | 1027 |

## Appendix E - Leisure activities figures

Table E. 1 - Regular leisure activities and overall SDQ score (2013)

|  | Boys |  |
| :--- | :---: | :---: |
|  | At least weekly | Less often |

| Go to a concert or gig | 1,324 | 13,776 |

## Appendix F - Regression

## Interpreting Logistic Regression models

Table F1a shows the output for the logistic regression model for girls in 2013 in relation to borderline/abnormal versus normal score for three components of SDQ - emotion, conduct and hyperactivity components of SDQ. The first two columns indicate the different predictor factors included in the model. All variables have been treated as categorical variables.

Logistic regression models compare different categories against a reference category. In Table F1a, large urban area has been set as the reference category for the urban/rural classification, and the other categories are a series of comparisons with this category.

The columns headed 'Sig.', shows whether the factor is significant. A value of less than 0.05 in these columns suggests that this factor is significant. In Table F1a, the figure for 'other urban areas' (vs. large urban areas) for the emotion components is less than 0.05 , it follows that - after controlling for the effect of all other factors in the model - the likelihood among people living in other urban areas of having an abnormal/borderline score for emotion is different from the likelihood among those in large urban areas. Significant factors are highlighted in yellow in the tables.

The column headed 'Beta' indicates the direction of the effect. A positive value indicates that those in the category are more likely to have an abnormal/borderline SDQ score and vice versa. For example, those in other urban areas were more likely than those in large urban areas to have an abnormal/borderline score for emotion.

The column headed " $\operatorname{Exp}(\mathrm{B})$ " gives the odds ratio. This indicates the size of the effect. The further above 1 that the odds ratio is, the greater the increase in likelihood of using at least one substance. The further below 1, the greater the decrease in the likelihood of using at least one substance. A value of 1 for the odds ratio means that a factor has no effect. (The odds ratio is the inverse natural log of the Beta value. For example, the 'other urban areas' compared to 'large urban areas' in the emotion component of Table F1a, the beta value is 0.25 . The inverse of the natural $\log$ of $0.25-\operatorname{Exp}(0.25)$ - is 1.28 . This is the odds ratio.)

In the following tables, where a factor is significant, we have colour coded the odds ratios to give an indication of the size of the effect.

Figure F1: Key to colour coding of log odds

| Large increase in likelihood: $(\operatorname{Exp}(B)>1.67)$ |  |
| :--- | :--- |
| Some increase in likelihood: $(1<\operatorname{Exp}(B)<1.67)$ |  |
| Some decrease in likelihood: $(0.6<\operatorname{Exp}(B)<1)$ |  |
| Large decrease in likelihood: $(\operatorname{Exp}(B)<0.6)$ |  |

Note that for factors that are significant, it follows that ranges of likely values for the odds ratio (the values within the associated confidences internals) will all be either above or all below 1. The $95 \%$ confidence intervals can be calculated by taking the inverse of the natural $\log$ of the Beta values plus/minus 1.96 * of the standard error. This calculation is shown below for the upper and lower confidence intervals of the odds ratios of 'other urban areas' compared to 'large urban areas' in the emotion component:

- Upper and lower Cls of odds ratio = inverse of natural log of Beta +/- 1.96 * se.
- Beta $=0.25$ and se is 0.05 .
- So inverse of the natural log of $0.25+/-1.96$ * 0.05 .
$=$ inverse of natural log of 0.10 and of 0.35 $=1.16$ and 1.42 .

Table F1a: Logistic regression model of girls in 2013: borderline/abnormal versus normal score for the emotion, conduct and hyperactivity components of SDQ

|  |  | Emotion |  |  |  | Conduct |  |  |  | Hyperactivity |  |  |  |

[^0]:    ${ }^{1}$ These figures are based on sample sizes of 7,695 and 8,401 giving confidence intervals of around $+/-1 \%$. As such, this difference is clearly significant.

[^1]:    ${ }^{2}$ Mean score (as opposed to the median score).

[^2]:    ${ }^{3}$ Inverclyde and Renfrewshire have been excluded due to small base sizes.

[^3]:    I Base: Emotion (30400) Conduct (30434) Hyperactivity (30360) Peer problems (30384) Pro-social (30518)
    L - - -

[^4]:    ${ }^{4}$ In this instance, average knowledge is represented by the median score, rather than the mean.

[^5]:    | Base: Emotion (30880) Conduct (30918) Hyperactivity (30843) Peer problems (30865) Pro-social (30997) I

[^6]:    ${ }^{7}$ Answers in the 'other' category includes youth training, unemployed, don't know and those that said other.

[^7]:    ${ }^{8}$ Some of these postcodes were incorrect due to scanning errors and were manually edited rather than imputed
    ${ }^{9}$ http://www.nrscotland.gov.uk/statistics-and-data/statistics/statistics-by-theme/population/population-estimates/special-area-population-estimates/population-estimates-by-simd-2012

[^8]:    I Base: Overall SDQ (31002) Emotion (31089) Conduct (31126) Hyperactivity (31051) Peer problems (31074) |

[^9]:    ${ }^{10}$ Analysis was limited to 2013 due to the changes in the prevalence of borderline or abnormal scores across time.

[^10]:    ${ }^{11}$ This table is based on the logistic regression models reported in Tables F1a and F1b in Appendix F. "Yes, a lot" indicates log odds of less than 0.6 or greater than 1.67. "Yes, some" indicates log odds between 0.6 and 1.67 but a significant effect.
    ${ }^{+}$indicates that it may be a non-linear relationship or that the direction of the effect is not what might be assumed.
