1. Definitions

Academic year	The year from 1 August to 31 July. Throughout the publication this is denoted in the format '2012/13' to describe the year from 1 August 2012 to 31 July 2013.
Advanced Learner Loan (ALL)	A fee loan payable to Further Education (FE) providers on behalf of FE learners who meet the eligibility criteria and started a FE course on or after 1 August 2013.
Cancelled loans	The borrower no longer has any liability to repay as provided for in the loans regulations. A borrower's liability is cancelled: <ul style="list-style-type: none"> • On the death of the borrower; • On reaching the age or length of time cancellation criteria for their loan (which varies by loan product); or, • If borrower is in receipt of a disability related benefit and permanently unfit for work.
Capitalised interest	The interest accrued on student loans is added to a borrower's loan balance, rather than requiring repayment at the time it is accrued.
Doctoral loan	Loans issued to students on doctoral courses, on the Plan 3 repayment system. They are paid directly to students and can be used to cover fees or living costs.
Domicile	The usual residence of a student in the period prior to commencement of study. The financial support available to students from Government can vary for students from different domiciles. This publication includes forecasts of entrant numbers for English and EU domiciled students. Wherever 'EU domiciled' students are referred to this includes students domiciled in countries other than the UK that count as EU domiciled for funding purposes.
Entrants	Students in their first year of study. Defined as those starting a course in the academic year who have not been active at the same broad level of study at the same provider in either of the two previous academic years.
Face value of loan book	The total outstanding balance of the loan book. This will include all previous loan outlay and accrued interest, less any repayments or loan cancellations.
Financial year	The year from 1 April to 31 March. Throughout the publication this is denoted in the format '2012-13' to describe the year from 1 April 2012 to 31 March 2013. Some aspects of the student loan system are based on tax years (the 12 month period starting on 6 April), but as a simplification the student loan models assume that this is the same as the equivalent financial year.
Fully repaid loan	The borrower has repaid the loan in full during their repayment term without it being cancelled.
Higher education full-time loan	Loans available to students on full-time higher education courses, including first degrees, sub-degrees and certain postgraduate courses (e.g. Postgraduate Certificate in Education or PGCEs) that are eligible for the undergraduate loan system
Higher education part-time loan	Loans available to students on part-time higher education courses with an intensity of 25% or higher.

Income Contingent Repayment (ICR) loan	Loans for which the required repayments are based on the borrower's income. The type of student loan that has been available to students since 1998.
Liable to make repayments	The borrower has a remaining loan balance and has reached their Statutory Repayment Due Date (SRDD).
Maintenance loan	Maintenance loans are loans to cover living costs, paid directly to the student.
Master's loan	Loans issued to students on master's courses, on the Plan 3 repayment system. They are paid directly to students and can be used to cover fees or living costs.
Plans 1, 2 and 3	<p>The ICR loan scheme has been separated into different repayment arrangements called Plans 1, 2 and 3. While they operate in a similar manner, they differ in some ways such as the repayment thresholds, interest rates and the length of borrowers' repayment terms.</p> <p>Plan 1 is the loan system for undergraduate students that started courses before September 2012, Plan 2 the system for undergraduates since September 2012 and for Advanced Learner Loans, and Plan 3 the system for postgraduate loans introduced in 2016.</p>
Resource Account Budgeting (RAB) charge	Used in the DfE annual accounts, this is the proportion of loan outlay that is expected to not be repaid when future repayments are valued in present terms.
Repayment term	The period for which a loan borrower is liable to make repayments based on their income. At the end of a borrowers' repayment term any remaining loan balance is cancelled.
Repayment threshold	The annual income threshold above which borrowers are required to make repayments on any eligible income. Plan 1 and Plan 2 loan borrowers are required to pay 9% of any earnings above the threshold and Plan 3 borrowers will be required to repay 6%.
Statutory Repayment Due Date (SRDD)	The point a borrower becomes liable to begin repaying a loan, normally the start of the tax year (6 April) after graduating or otherwise leaving their course. After the SRDD borrowers are required to make repayments if their income is above the repayment threshold.
Stock charge	Used in the DfE annual accounts, this is the proportion of the total outstanding face value of the loan book that is expected to not be repaid when future repayments are valued in present terms.
Tax year	The 12 month period starting on 6 April. As a simplification, the student loan models assume that this is the same as the equivalent financial year running for 12 months from 1 April. Repayment thresholds are fixed for the duration of each tax year and borrowers' SRDDs are at the start of the tax year after they graduate or otherwise leave their course.
Tuition fee loan	Tuition fee loans are loans to cover all or part of the cost of tuition. They are paid directly to the learning provider.
Voluntary repayment	A borrower can at any time choose to repay some or all of their loan balance early, in addition to any repayments they are liable to make based on their income.

2. Background

Introduction

Income Contingent Repayment (ICR) student loans are provided by Government to higher education students and some further education students to cover course fees and living costs while they are studying. They were first introduced in the UK for new undergraduate students in 1998, at the same time as tuition fees. Prior to 1998, university students were provided funding by Government through a mixture of grants and, from 1990, mortgage style loans that were available to help with living costs. Mortgage style loans are not covered in this publication.

Each of the four constituent countries of the UK now have their own student loan policies, but only English student loans are considered in this publication. These are loans issued to English domiciled students that attend any learning provider in the UK and EU domiciled students that attend learning providers in England. A summary timeline of income contingent repayment loans is available in Table 2.1 below.

Table 2.1: Income Contingent Repayment loan timeline: England

1998	<ul style="list-style-type: none"> Plan 1 loans introduced for new UK domiciled undergraduate students, to cover living costs Annual tuition fee of up to £1,000 also introduced in 1998 Teaching and Higher Education Act.
2006	<ul style="list-style-type: none"> Maximum annual tuition fee increased to £3,000 for new entrants Tuition fee loans introduced EU domiciled students became eligible to take out tuition fee loans Repayment term changed to 25 years for new entrants, rather than ending at age 65
2012	<ul style="list-style-type: none"> Plan 2 loans introduced for new entrants Maximum annual tuition fee increased to £9,000 for new entrants Part-time undergraduates become eligible for tuition fee loans
2013	<ul style="list-style-type: none"> Advanced Learner Loans introduced for students aged 24+ on some further education courses, on the Plan 2 system
2016	<ul style="list-style-type: none"> Plan 3 loans introduced for new students taking master's courses, who could borrow up to £10,000 over the length of their course Maintenance grants replaced by additional maintenance loans for new undergraduate entrants on lower incomes Advanced Learner Loans extended to students aged 19-23
2017	<ul style="list-style-type: none"> Nursing, midwifery and most allied health students become eligible for student loans, in place of receiving NHS bursaries
2018	<ul style="list-style-type: none"> Plan 2 repayment threshold increased from £21,000 to £25,000. It had previously been announced that it would remain at £21,000 until April 2021 Doctoral loans of up to £25,000 across the length of a borrower's course introduced, on the Plan 3 system Maintenance loans introduced for part-time undergraduates, initially for on-campus, degree-level students before being extended to distance learners and sub-degree students in 2019

Student loans are issued by and administered by the Student Loans Company (SLC) on behalf of the Government and the devolved administrations in the UK. The Department for Education produces forecasts

for its outlay on and the repayments it expects to receive from the English student loans that it is responsible for. These are for use in financial planning, policy development and to value the loans that have been issued in its annual accounts. The forecasts presented in this publication are produced by four models, as follows:

- Student loan outlay model – this model produces forecasts for loan outlay on higher education ICR loans, including those issued to undergraduates and postgraduate students.
- Student loan repayment model – this model produces forecasts for the future repayments that will be made by higher education ICR loan borrowers.
- Student numbers model – this model forecasts the number of full-time undergraduate entrants eligible for Office for Students funding in England. These forecasts are used in the student loan outlay and repayment models to estimate the future growth in full-time loan borrower numbers.
- Advanced Learner Loans model – this model produces forecasts for loan outlay and repayments that will be made on Advanced Learner Loans, which are available for some further education courses.

This document provides information on these four models, including the methodology, data sources and assumptions used in producing the forecasts.

3. Student loan outlay model

Introduction

The student loan outlay model forecast loan amounts that the Department for Education (DfE) expects to pay higher education students (and their providers) via the Student Loans Company (SLC).

A range of sub-models are used to capture the various loan types available to students on higher education courses. The loan products that outlay forecasts are produced for are:

- Plan 1 loans – the loan system for students that started courses before September 2012 that are eligible for undergraduate student support funding, consisting of fee loans and maintenance loans.
- Plan 2 full-time loans – the loan system for students on full-time courses that started since September 2012 that are eligible for undergraduate student support funding, consisting of fee loans and maintenance loans.
- Plan 2 part-time loans – the loan system for students on part-time courses that are eligible for undergraduate student support funding. These first became available in September 2012, consisting of a tuition fee loan. From August 2018 maintenance loans will also be available to some part-time students.
- Master's loans – loans available to master's students to help cover fees and living costs. They were introduced in August 2016 and are on the Plan 3 repayment system.
- Doctoral loans – loans that will be available to doctoral students from August 2018 to help cover fees and living costs. They are on the Plan 3 repayment system.

Documents detailing the availability and the student finance package for each loan product can be found at the Student Finance England Practitioners' Website: <https://www.practitioners.slc.co.uk/policy/>

The higher education student finance package for undergraduates is covered in detail in the *Student Finance Arrangements for Undergraduates* document and all rates of support are detailed in the *Financial Memorandum*. The eligibility criteria can be found in the *Assessing Eligibility guidance* document.

Eligible English domiciled students are entitled to fee and maintenance loans for courses that are eligible for undergraduate funding. Eligible EU domiciled students are entitled to fee loans only. Both are entitled to the same amount for postgraduate loans.

Plan 1 and Plan 2 loans

The fee and maintenance loan levels available to students are typically already known for the first two academic years for which the model produces forecasts, currently 2017/18 and 2018/19. Maximum fee amounts in 2018/19 were set at the same levels as in 2017/18, while maintenance loan entitlements were increased in line with the March 2017 Office for Budget Responsibility (OBR) RPIX forecast for the Jan-Mar 2019 quarter.

The maximum fee caps in 2017/18 funding was maintained at £6,000 for the basic amount, or at £9,000 for the higher amount for those without a Teaching Excellence and Student Outcomes Framework (TEF) rating and £6,165 and £9,250 for those with a TEF rating for full-time courses that are eligible for undergraduate student support. Providers eligible to charge the higher amount are currently referred to as Core Providers in the model and those eligible to charge the basic amount currently referred to as Alternative Providers in the model. From 2019/20 a higher education provider in England will be required to register with the Office for Students (OfS) if it wishes to access student support funding. The OfS register will contain two categories, approved (fee cap) and approved. Providers registered as approved (fee cap) will be able to charge tuition fees up to the higher amount and those registered as approved will be able to charge tuition fees up to the basic amount¹.

¹ Details can be found here: https://www.officeforstudents.org.uk/media/1406/ofs2018_01.pdf

Maintenance loans for eligible students depend on their location and household income (where a borrower applies for a means tested loan). The maximum maintenance loan for full-time Plan 1 borrowers, living away from home and studying outside of London, in 2017/18 is £5,440². The maximum maintenance loan for full-time Plan 2 borrowers, living away from home and studying outside of London, in 2017/18 is £8,430³. Table 1A of the Student Loans Company statistical publication [Student support for Higher Education in England](#) presents the maximum rates of maintenance loans and tuition fee loans for full-time students domiciled in England.

Maintenance loans will be available in 2018/19 to part-time, on-campus, degree students. This will be extended to distance-learning and sub-degree students in 2019/20. These loans mirror the full-time maintenance loan, with the intensity of study taken into account alongside means testing and location. Students studying courses at less than 25% intensity will not be eligible for part-time maintenance loans.

Postgraduate master's loans

The postgraduate master's loan was introduced in 2016/17. Eligibility for a master's loan depends on the duration and intensity of the student's course, their age on the first day of the first academic year of their course, and their nationality or residency status. The course must also be provided by a university or college in the UK, which is either publically funded or a designated private provider.

Unlike undergraduate loans, master's loans for eligible students depend on the start date of their course, rather than location or household income. The maximum master's loan for a course starting in 2017/18 is £10,280 across the length of the course.

Postgraduate doctoral loans

The postgraduate doctoral loan will be introduced in 2018/19. Eligibility for a doctoral loan is based on duration of the student's course, their age on the first day of the first academic year of their course, and their nationality or residency status. The course must also be provided by a university or college in the UK, which is either publically funded or a designated private provider.

The maximum doctoral loan amount in 2018/19 is £25,000 across the length of the course.

Methodology

Student loan outlay for existing higher education loan products is forecast based on historical data from the Student Loans Company. For new loan products, where historical information is not available, an alternative forecasting method is required.

Existing higher education loan products

The student loan outlay forecasts for existing higher education loan products use historical outlay from the Student Loans Company. The historic outlay is projected into the future using the entrant growth from the Department's student entrants model; projected take-up rates; historic continuation rates (the probability that a borrower will continue to receive a loan in the following academic year); OBR RPIX forecasts and Office for Fair Access (OFFA) estimates of the average fee after waivers. Where future policies are announced an assessment is made on the impact of the policy on the borrower numbers and average loans and the forecasts are adjusted accordingly.

The model forecasts various homogenous subpopulations of students separately, to improve the accuracy of the forecast. For the products with the largest outlay a cohort-based model is used for the academic year forecast.

The cohort approach involves predicting future borrowers and average loan amounts by cohort (determined by course start year and academic year). Future borrowers are forecast by taking existing borrower

² Loans for living costs of continuing students who started attending full-time courses before 1 September 2012 who are living away from home and studying outside London

³ Loan for living costs for new full-time students and full-time students starting their courses from 1 August 2016 onwards who are continuing their courses in 2017/18 who are living away from home and studying outside London.

numbers, by cohort, and applying a growth rate (a combination of the growth from the student numbers model and growth in the take-up rate of the loans) to new students. Historic continuation rates are calculated from the previous two academic years for existing cohorts to determine the number of borrowers in the next academic year, by cohort.

The average loan amounts are forecast by taking the most recently available average loan amounts by cohort and uprating them by forecast RPIX for maintenance loans and fee loans, as this is how borrowers' maximum fee and maintenance loan entitlements are usually uprated each year. For average fee loan amounts the growth in the OFFA estimate of average fee loans after waivers is used instead of forecast RPIX in years where it has been announced that the maximum tuition fee amounts are being frozen at the same levels as the year before. This allows for fee amounts still changing in these years on courses where the maximum fee is not being charged.

The student numbers and average loan amounts are then multiplied together to give the total outlay for a particular loan product and subgroup. The cohort approach is used for the following subgroups;

- full-time English fee loans for providers eligible to charge the higher amount on non-PGCE courses
- full-time EU fee loans for providers eligible to charge the higher amount on non-PGCE courses
- part-time fee loans providers eligible to charge the higher amount and basic amount
- full-time English maintenance loans providers eligible to charge the higher amount on non-PGCE courses

An example of the cohort approach for the full-time English fee loans for providers eligible to charge the higher amount on non-PGCE courses subgroup is provided in Figure 3.1, on page 9. Figures provided are for illustrative purposes.

For full-time fee and maintenance loans at providers eligible to charge the basic amount (currently known as Alternative Providers) the method above is used to forecast entrant borrower numbers. Instead of using historic continuation rates by cohort it is assumed that the number of continuing borrowers is equal to 90% of the borrowers who were entrants in the previous academic year. The average loan amounts are also forecast using the same method as above, but for all borrowers. The average loan amounts are then multiplied by the total number of borrowers to give the outlay for these subgroups.

For the remaining subpopulations, the total outlay from the previous year is multiplied by year forecast RPIX (or the growth in the OFFA estimate of average fee loans after waivers where a fee freeze has been announced). The borrower numbers are assumed to be constant. This includes full-time fee and maintenance loans for PGCE courses at publicly funded providers.

Loans outlay is forecast for academic years and financial year forecasts are calculated from these. The financial year forecast uses historical SLC payment information by month to incorporate the profile of academic year payments across financial years. The financial year forecast is based on the monthly payment from the previous year multiplied by the year on year growth in the academic year forecast.

Figure 3.1: Example of cohort modelling

Step 1: Forecast the number of borrowers in the next academic year.

A: Input historic SLC borrower numbers

Year of course	Academic Year	
	2015/16	2016/17
1 st	325,000	330,000
2 nd	280,000	280,000
3 rd	230,000	235,000
4 th	60,000	75,000
5 th	10,000	10,000
6 th	1,000	1,000
Total	906,000	931,000

Data from the SLC for the latest two academic years. The table shows the number of borrowers in each year of their course.

B: Forecast borrower transitions (continuation rates)

Transition	Calculation (000's)	Continuation rate
1 st to 2 nd year	280/325	86%
2 nd to 3 rd year	235/280	84%
3 rd to 4 th year	75/230	33%
4 th to 5 th year	10/60	17%
5 th to 6 th year	1/10	10%

The transition of borrowers (B) from academic course year to the next is calculated from the latest two academic years where there is historic SLC data (A).

For example, the transition from the 1st to 2nd year (86%) is the number of 2nd year borrowers in 2016/17 divided by the number of 1st year borrowers in 2015/16 (280,000/325,000, shown in blue).

C: Forecast borrower numbers

Year of course	Academic Year 2017/18
1 st	334,950 (=330,000 × 1.015)
2 nd	284,308 (=330,000 × 0.86)
3 rd	235,000 (=280,000 × 0.84)
4 th	76,630 (=235,000 × 0.33)
5 th	12,500 (=75,000 × 0.17)
6 th	1,000 (=10,000 × 0.10)
Total	944,388

To forecast new borrowers in the first year of their course the number of new borrowers from the previous year in the historic data in table A is multiplied by the forecast entrant growth from the student numbers model (1.5% in 2017/18).

To forecast continuing borrowers (i.e. not in 1st year of course) the number of borrowers in the previous academic year from table A is multiplied by the continuation rate for that transition. For example, the number of 2nd year borrowers in 2017/18 is the number of 1st year borrowers in 2016/17 multiplied by the 1st to 2nd year transition from table B (330,000 × 86%, shown in blue).

Step 2: Forecast the average loan amount for each year group in the next year

Multiply average loan in previous year by forecast RPIX (3.2% for 2017/18)

Year of course	Average loan 2016/17	Average loan 2017/18
1 st year	£8,500	£8,772
2 nd year	£8,500	£8,772
3 rd year	£8,000	£8,256
4 th year	£8,500	£8,772
5 th year	£8,000	£8,256
6 th year	£8,000	£8,256

Step 3: Forecast the loan outlay

Multiply number of borrowers (from step 1) by average loan (step 2). For example, the outlay for 1st year borrowers is £2.938m (334,950 × £8,772).

Year of course	Forecast outlay 2017/18 (£m)
1 st year	£2,938
2 nd year	£2,494
3 rd year	£1,940
4 th year	£672
5 th year	£103
6 th year	£8
Total	£8,156

Master's loans

Due to their recent introduction in 2016/17, historic master's loan borrower data is limited such that it is not possible to forecast future loan outlay using the same approach as for undergraduate loans. Instead, master's loan forecasts rely on 2013/14 Higher Education Statistics Agency (HESA) student data characterising age, domicile, course duration, intensity of study, mode of study and numbers of master's students not receiving financial support. Using the assumptions outlined in Table 3.1, estimates of the total number of students who are likely to take up a loan each academic year from 2017/18 are generated. The number of loan borrowers in 2016/17 (the year the loans were introduced) is supplemented by an in-year snapshot from SLC data in September 2017.

Table 3.1: Core assumptions feeding into master's loan volume estimates

Parameter	Assumption
Loan take-up	75% of students who would normally self-fund
Deferral	10% of students would defer their studies from 2015/16 to 2016/17
Number of additional students expected to take up study due to availability of the loan	An additional 10% of under 30 student numbers would be expected An additional 7.1% of students aged 30-35 would be expected An additional 6.4% of students aged 36 or over would be expected
Part-time behaviour change	20% of students on low-intensity courses would choose a higher intensity course in order to qualify for the loan
Growth rates	Based on HEFCE forecasts until 2017/18 2% steady state growth assumed from then
3-year part-time (no full-time equivalent) Open University courses	An additional 2,635 students that are not captured in the volumes data

Annual academic year loan outlay is calculated using a cohort approach, as detailed in Figure 3.1, based on start year and the proportion of students within each course duration, calculated using in-year SLC data for the 2016/17 borrowers. The expected number of loan borrowers in each cohort is multiplied by a corresponding average loan amount, based on in-year SLC data for the 2016/17 borrowers and updated by OBR forecast RPIX in each year. The sum of the outlay from each cohort is aggregated to produce a final academic year outlay figure. Financial year outlay is then calculated using the assumption that two thirds of the yearly loan amount each academic year is given in the first financial year it overlaps with (covering loan outlay from August to March), and the remaining third in the following financial year (covering April to July).

Part-time maintenance loans

Part-time maintenance loans are being introduced in academic year 2018/19 for on-campus degree level students and in 2019/20 for students on other eligible part-time courses. Loan outlay is forecast based on stock flow assumptions, whereby entrants flow into the system, continuation assumptions are applied to estimate their length of time in study and subsequently build up the stock of enrolments. Loan take-up assumptions are applied to these enrolment volumes, and the estimated take-up volumes are multiplied by the average loan amount to estimate the total outlay on an academic year basis. This mirrors the cohort modelling approach detailed above.

The part-time maintenance loans model takes the total part-time student population in the UK as a whole, based on historical HESA data up to 2015/16, and uses HESA 2015/16 entrant proportions to split the base population into three components:

1. Degree (level 6), on-campus = 9% of total
2. Sub-degree (levels 4 & 5), on-campus = 56% of total
3. Levels 4-6, distance learning = 35% of total

From 2019/20, base entrant numbers are assumed static at 110,000, based on the assumption that HESA 2015/16 volumes for part-time student numbers remain constant. As this loan is only eligible for on-campus degree level courses in academic year 2018/19, eligible entrant volumes for this year are set at 9,900 (9%

× 110,000). In modelling the introduction of this loan, it is assumed that there will be additional students incentivised to take on part-time study due to the availability of this support. This behavioural effect is modelled by assuming 900 additional students in 2018/19⁴; 10,000 in 2019/20; 15,000 in 2020/21 and a static 25,000 subsequently⁵. These numbers were modelled to bring the total student volumes halfway towards what they would have been had the pre-2008 trend continued.

Average fee loan payment estimates are required to estimate the total loan outlay. A simplified description of the average loan calculation methodology for academic year 2018/19 can be found in Table 3.2 below. Average loan values for subsequent years are updated using OBR RPIX forecasts, assuming that the characteristics of students taking up these loans do not change year-on-year.

Table 3.2: Summary of average loan calculation for part-time maintenance loans

Methodology	Assumption
Identify location-based maximum loan	£7,097 for students living at home (8%)
	£8,430 for students living elsewhere (71%)
	£11,002 for students living in London (21%)
Include means testing assumptions	33% assumed maximum loan (based on previous part-time system)
	9% assumed receiving means-tested loan below the maximum
Include study intensity assumptions	Use HESA 2015/16 proportional breakdowns of intensity of study (reflecting the proportion of time spent in study relative to a full-time student)

Annual academic year loan outlay is calculated using the aforementioned cohort approach, based on continuation rates estimated from HESA cohort data and the proportion of students estimated to take up each component of part-time study as outlined above, multiplied by take-up assumptions. The expected number of loan borrowers in each cohort is multiplied by the corresponding average loan amount, with the sum of the outlay from each cohort aggregated to produce a final, academic year outlay figure. Financial year outlay is then calculated using the assumption that half of the yearly loan amount each academic year is given in the first financial year it overlaps with and the second half in the following financial year.

Doctoral Loan

Doctoral loans will be introduced in academic year 2018/19. The model uses 2014/15 HESA student data to estimate take-up. Students who are currently self-funded are the population assumed to qualify for this loan product. Further assumptions used to refine these estimates are predictions for take-up (72% of those eligible), students above the age cap (2%), growth rates based on OfS estimates, and an estimate of the proportion of students who will take up postgraduate research study due to the availability of this loan (10% of all students below 60).

The average loan taken out is estimated to be £25,000, which is the maximum that borrowers starting in 2018/19 are eligible to receive. Annual academic year outlay is then calculated using a cohort approach, based on continuation rates estimated from HESA cohort data and the proportion of students estimated to take up a doctoral loan as outlined above. The expected number of loan borrowers in each cohort is multiplied by the corresponding average loan amount, with the sum of the outlay from each cohort aggregated to produce a final academic year outlay figure. Financial year outlay is then calculated using the assumption that two thirds of the yearly loan amount each academic year is given in the first financial year it overlaps with and the remaining third in the following financial year.

⁴This is based on the undergraduate take-up assumptions, where around 88% take a maintenance loan and around 92% take a fee loan.

⁵ All additional students are assumed to also take up a part-time fee loan, and are factored into the existing part-time fee loan estimates.

Data quality

Producing forecasts is inherently uncertain and they are very dependent on the data sources, modelling techniques and assumptions used in the model. In particular, the model assumes that the characteristics and behaviour of future borrowers will be similar to historic ones derived from SLC administrative data, which will not necessarily be the case.

The model is dependent on the OBR macroeconomic forecasts that it uses to uprate fee and maintenance loans. Any significant changes to the economy from these forecasts could affect the outlays that will be made on student loans.

The model uses SLC administrative data to determine borrower numbers and average loan amounts. The DfE receives data extracts from the Student Loans Company on an academic year basis that are used in the student loan outlay model. This data is consistent with the data published in the SLC Student Support for higher education in England publication, which can be found at the following webpage:

<https://www.slc.co.uk/official-statistics/financial-support-awarded/england-higher-education.aspx>.

SLC publishes a statement on its administrative sources here:

https://www.slc.co.uk/media/5450/slc_statistics_-_statement_of_administrative_sources.pdf.

SLC also publishes data quality guidelines on the following webpage: <https://www.slc.co.uk/official-statistics/guide-to-our-statistics/compliance.aspx>

The model uses the growth in the entrants from the DfE student numbers model. The student number model forecasts students eligible for Office for Students (formally HEFCE) funding, which is a different population to those who are eligible for student support. If the growths in these populations are not consistent then this will have an impact on the number of new entrants who are taking out loans in the model.

The OFFA estimates of the average fees after waivers that are used to estimate the growth in the average fee loan when the fees are frozen are based on providers with access agreements and their student number forecasts. Providers have to have an access agreement to charge the higher amount, however they do not need to charge the basic amount. The figures assumes a flat fee of £6,000 for FECs without access agreements. OFFA analysis of HEIFES data indicates that there are around 16,600 and 14,700 full-time higher education students at FECs without access agreements in 2017-18 and 2018-19 respectively.

The model assumes that fees and maintenance loans will be uprated by forecast RPIX in future years for which fee and maintenance loan levels have not yet been announced. The model also assumes that the current student finance policies will remain unchanged. Once policies have been announced they are incorporated into the model. Therefore, any changes to the student finance policy will affect future forecasts. In particular a review of post-18 education and funding is currently ongoing that could potentially lead to changes to the Government's student finance policy.

The forecasts for new loan products such as postgraduate loans and part-time maintenance loans are more uncertain as there is no historical SLC data on which to base the forecasts. Instead assumptions have to be made about the likely uptake of these products, which are more uncertain because the introduction of these products is likely to change student behaviours.

4. Student loan repayment model

Introduction

The DfE student loan repayment model is the financial model used to estimate the financial cost of income contingent student loans to Government. It forecasts the repayments that the Department expects to receive from its expenditure on student loans.

The model is a micro-simulation model. It forecasts student loan repayments by estimating future earnings for a population of individual student loan borrowers and then applying the loan repayment policy to each borrower, before aggregating the results to estimate totals for the population as a whole. For each loan borrower it uses equations to estimate their next year's earnings, and when these are used repeatedly this generates an earnings path. Where historical information on earnings is available the model makes use of this. Multiple equations are used in the model depending on the borrower's level of study, gender, years since SRDD and whether the borrower has been a low, medium, or high earner historically. This allows the model to capture individual changes in earnings over the borrower's working lifetime.

Once a borrower's earnings have been forecast their repayments, interest and loan balances are calculated year by year for the length of their repayment term, or until they finish repaying their loan. Further adjustments are made to some borrowers' repayments to allow for investment income, voluntary repayments, overseas repayments, direct debit repayments, incorrect amounts being repaid and loans being cancelled early due to death.

The model forecasts repayments for English domiciled students studying in the UK and EU domiciled students studying in England. Earnings forecasts are made for undergraduates (first degrees and sub-degrees) and PGCE loan borrowers based on historical administrative data for comparable loan borrowers and survey data on UK residents with a similar qualification level. For master's and doctoral loan borrowers earnings are modelled by applying a percentage uplift to an earnings forecast for a comparable first degree student.

The main data sources used in the model are:

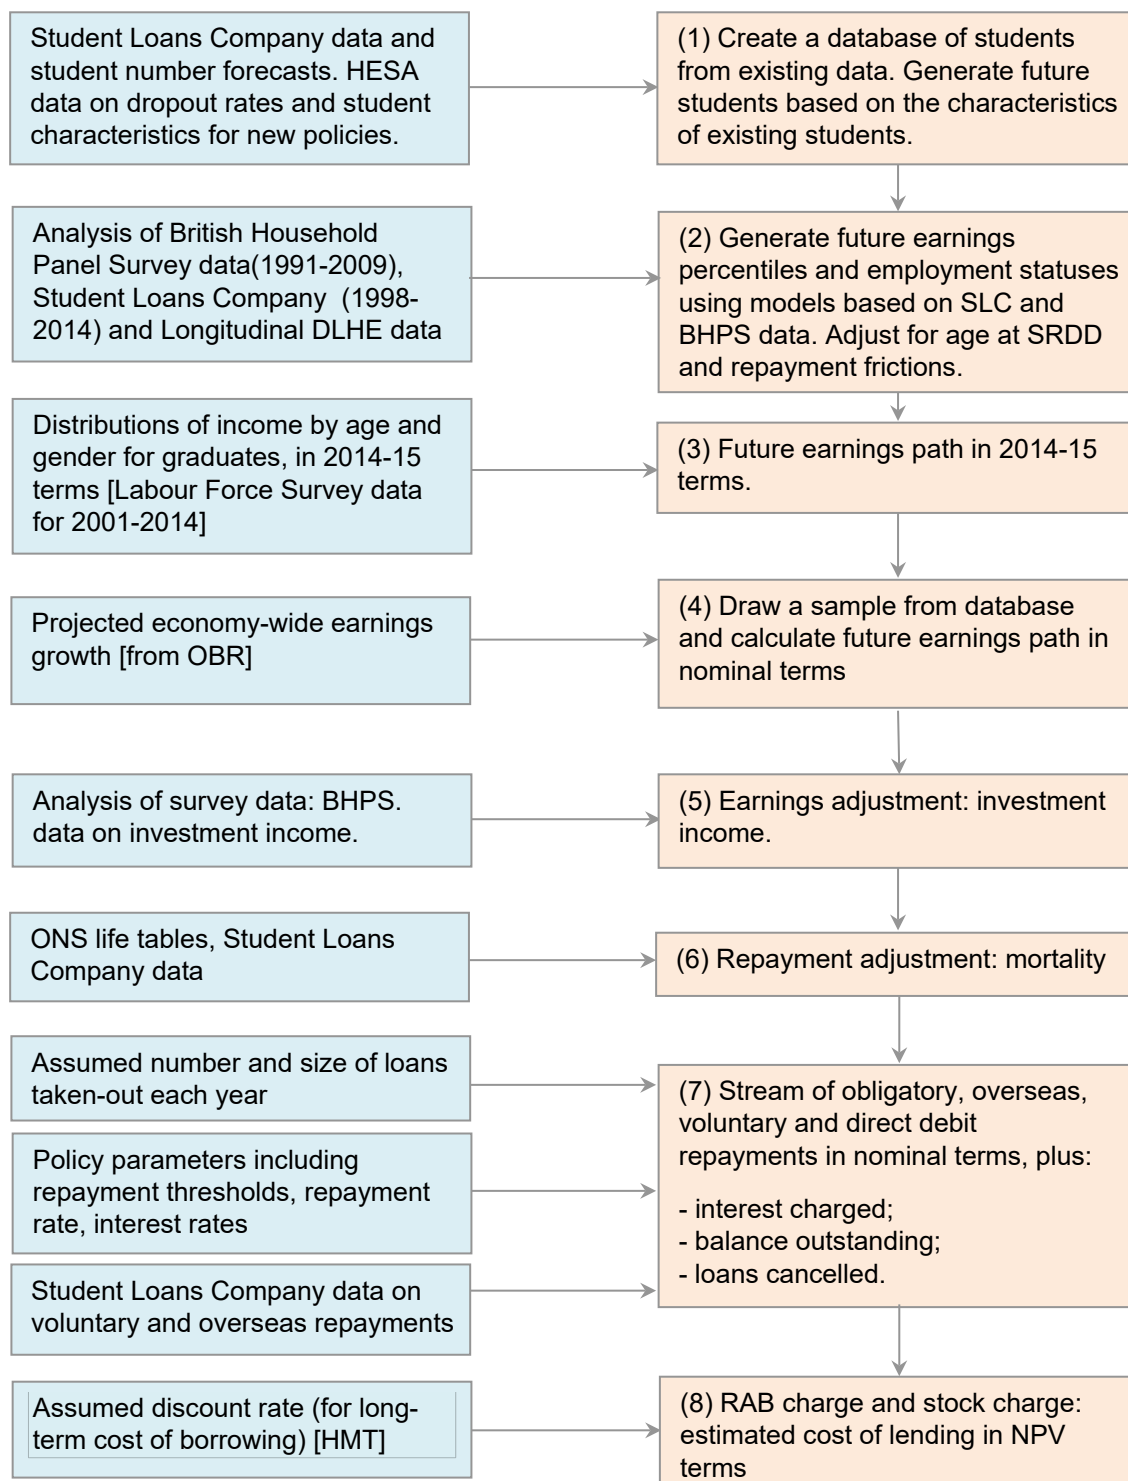

- Student Loans Company (SLC) administrative data – provides details of borrowers and the loans they take out, used to forecast earnings and employment status in early repayment years. Used for modelling migration, repayment frictions and repayments made directly to the SLC.
- British Household Panel Survey (BHPS) data – used in earnings and employment models in later repayment years.
- Labour Force Survey (LFS) data – to convert income percentiles to cash amounts, regarded as more reliable than cash values from BHPS due to large sample sizes.
- Destinations of Leavers from Higher Education (DLHE) survey – used in the graduate age adjustment.
- Office for National Statistics (ONS) life tables – data on deaths.
- ONS Average Weekly Earnings (AWE) data – used to adjust earnings between 2014-15 earnings values and nominal terms
- Higher Education Statistics Agency (HESA) data – course completion rates, characteristics information for borrowers taking out new loan products for which there is no historical SLC data.
- Office for Budget Responsibility (OBR) macroeconomic forecasts – forecasts of earnings growth, the Bank of England base rate, RPI and RPIX.
- DfE Student numbers model – forecasts of entrant numbers.

Figure 4.1 explains, at a high level, the processes that the model goes through to produce the forecasts, along with how each data source feeds into the full model.

Figure 4.1: Processes and sources underlying the student loan repayment model

Source of data and analysis

Flow of the student loan repayment model

Student loan repayment policies

ICR loans require borrowers to make repayments based on their annual income, starting from the April after they have left their course. Under each policy, borrowers are required to make repayments each tax year equal to a percentage of their income above a set repayment threshold until either they have fully repaid their loan balance or their loan is cancelled. Loans are cancelled if the borrower dies, if they still have an outstanding loan balance at the end of their repayment term, or if they are in receipt of a disability related benefit and permanently unfit for work. Loans accrue interest during and after their course, which is added to a borrower's loan balance.

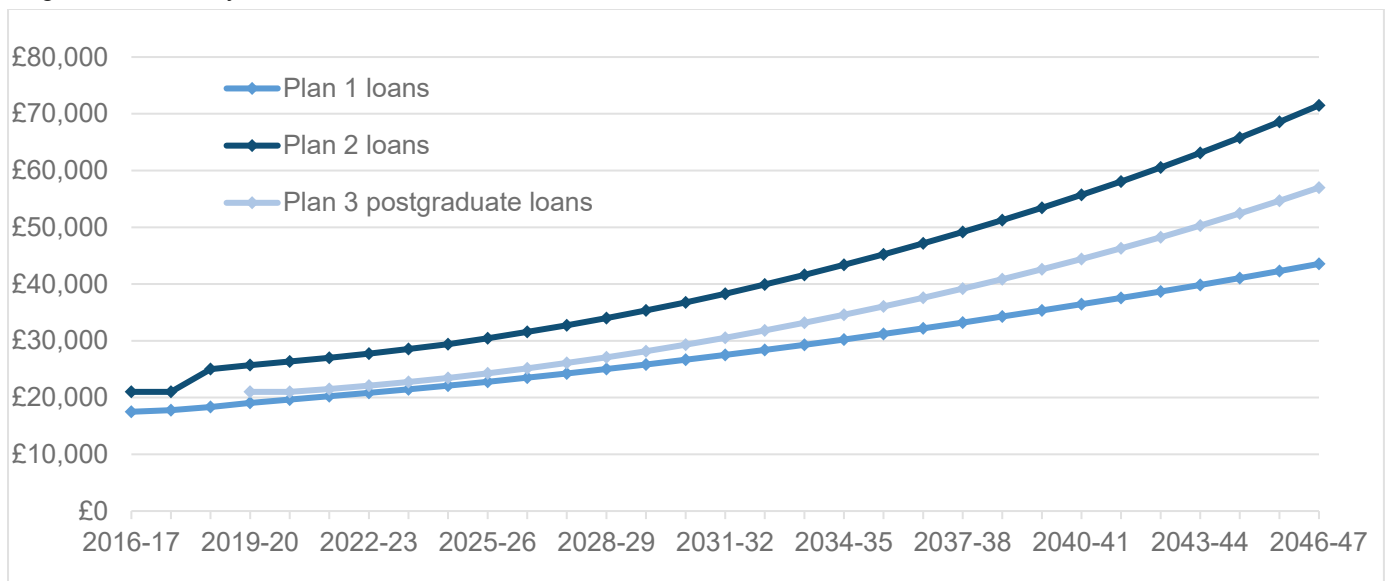

A borrower becomes liable to repay their loan in the 1 April after they complete (or otherwise leave) their course, at which point their repayment term starts on what is known as their Statutory Repayment Due Date (SRDD). There are two exceptions to this: 1) a part-time loan borrowers studying for longer than 4 years have an SRDD in the 5 April after the start of their course, even if they are still studying; and, 2) when a loan product is first introduced the earliest SRDD for some borrowers may be later than it would usually be. For example, all Plan 2 borrowers that completed or left their courses before April 2016 had an SRDD of April 2016, even though under the usual rule some would have had an SRDD up to three years earlier. A summary of the key repayment policy details for each loan product is shown in table 4.1 below.

Table 4.1: Key policy details for each loan product

	Plan 1	Plan 2	Plan 3 (Postgraduate)
Earliest year of entrants	1998/99	2012/13	2016/17 (master's) 2018/19 (doctorates)
Earliest SRDD cohort	April 2000	April 2016	April 2019 (master's) April 2020 (doctorates)
Length of repayment term	Until age 65 (entrants up to 2005/06); 25 years after SRDD (2006/07 entrants onwards)	30 years after SRDD	30 years after SRDD
Repayment rate	9% of earnings above repayment threshold	9% of earnings above repayment threshold	6% of earnings above repayment threshold (in addition to any Plan 1 or Plan 2 repayments)
Interest rate	The lower of either RPI, or the Bank of England base rate +1%	RPI+3% during course, variable between RPI and RPI+3% after SRDD depending on earnings	RPI+3%

Each loan product has a separate repayment threshold, above which repayments are made on any income. Figure 4.2 shows the forecast repayment thresholds for each policy. The Plan 1 threshold increases each year based on RPI. The Plan 2 threshold was initially £21,000 for two years before rising to £25,000 in 2018-19, after which it will increase in line with average earnings growth figures published by the Office for National Statistics (ONS). The Plan 3 repayment threshold will be £21,000 from when the first borrowers become liable to repay in 2019-20 until 2020-21, after which it will be reviewed. To enable future repayments to be forecast, for modelling purposes it is assumed that from this point it will rise in line with Office for National Statistics (ONS) average earnings growth statistics in the same way as the Plan 2 threshold. The student loan repayment model forecasts future repayment thresholds using OBR forecasts for RPI and average earnings growth.

Figure 4.2: Forecast repayment thresholds for each loan product
 England, financial years 2016-17 to 2046-47

In addition to the repayment threshold, Plan 2 also has two interest thresholds. Once Plan 2 borrowers are past their SRDD their interest rate varies depending on their income. If their income is below the lower interest threshold their interest rate is RPI, above the upper interest threshold it is RPI+3%, and for anyone with an income in between it varies linearly between the two. The lower interest threshold is the same as the repayment threshold, while the upper interest threshold was £41,000 in 2016/17 and 2017/18 before increasing to £45,000 in 2018-19. In subsequent years both thresholds will rise in line with ONS average earnings growth statistics.

Student loan borrowers resident in the UK generally make their loan repayments through the tax system to Her Majesty's Revenue and Customs (HMRC), either in-year through their employer via Pay As You Earn (PAYE) or the following year via a Self Assessment tax return. Borrowers resident overseas are required to contact the Student Loans Company (SLC) and arrange to make repayments directly to them. Borrowers can also choose to make early repayments on their loan directly to SLC, and when a borrower is close to fully repaying their loan SLC will alert them and, to avoid over-repaying via the tax system, they can arrange to make their repayments via direct debit directly to SLC rather than through HMRC.

Methodology

Loan borrower population

A population of past and future loan borrowers is created containing information about borrowers' loan amounts, their courses, and various other information about them. To forecast a borrower's earnings the model needs data on their characteristics such as:

- Higher education provider group (see Table 4.2)
- subject group, based on subject area codes defined by HESA⁶ (see Table 4.3)
- course level: sub-degree, first degree and PGCE level
- age,
- SRDD, and
- up to three years of actual earnings and employment history, where available.

⁶ Further details on subject area codes are available from HESA: [JACS 3.0: Principal subject codes](#)

Table 4.2: Provider groups used in student loan repayments model

Provider group	Example of providers in group (not an exhaustive list)
Russell Group	Oxford, Cambridge, Leeds, Manchester, Nottingham, Birmingham, Sheffield, Cardiff, Southampton, Newcastle, Liverpool, Edinburgh, Queens (Belfast), Durham, Exeter, Bristol
1994 Group	Loughborough, East Anglia, Leicester, Lancaster, Sussex, Essex, Goldsmiths, Royal Holloway, IoE, SOAS, Birkbeck
University Alliance	Manchester Metropolitan, Sheffield Hallam, Nottingham Trent, UWE, Liverpool John Moores, Northumbria, Plymouth, De Montfort, Portsmouth, Kingston, Hertfordshire
MillionPlus	Leeds Metropolitan, Central Lancashire, Wolverhampton, Middlesex, Birmingham City, London Metropolitan, East London, Staffordshire, Derby, Sunderland
GuildHE	Southampton Solent, Worcester, York St John, Winchester, Chichester and many arts university colleges
Large non-affiliated	Brighton, Hull, Westminster, Kent, Edge Hill, Brunel, Strathclyde, Reading, Swansea, Roehampton, Gloucestershire, Bath, Heriot-Watt
Small non-affiliated	Numerous small colleges

Table 4.3: Course subject classification with typical subjects of study

Subject group	Typical subjects
Medicine and Dentistry	Medicine, Dentistry (both pre-clinical and clinical)
Subjects allied to Medicine	Anatomy, Pharmacy, therapies, nutrition, optometry, audiology, nursing, medical technology, environmental health
Biological Sciences	Biology, botany, zoology, genetics, microbiology, sport and exercise science, biochemistry, psychology
Veterinary Sciences, Agriculture	Veterinary Medicine and Dentistry (both pre-clinical and clinical), animal science, agriculture, forestry, food studies
Physical Sciences	Chemistry, Materials Science, Physics, Forensic Science, Astronomy, Geology, marine sciences, physical geography
Mathematical Sciences	Mathematics, Operational Research, Statistics
Engineering	General engineering, civil engineering, mechanical engineering, aerospace engineering, naval architecture, electrical engineering, production engineering, chemical engineering
Computer Sciences	Computer science, Information systems, Software engineering, Artificial Intelligence, health informatics, Games, Computer-generated audio & visual effects
Technologies	Minerals technology, Metallurgy, Ceramics & Glass, Polymers, Textiles, Materials technology, Maritime technology, biotechnology
Architecture, Building & Planning	Architecture, Surveying, Building, Landscape design, Planning
Social Studies	Economics, Politics, Sociology, Social Policy, Social Work, Anthropology, Human geography, Development studies
Law	Law by area, law by topic
Business & Administrative Studies	Business Studies, Management, Finance, Accounting, Marketing, HR management, office skills, hospitality/tourism
Mass Communication and Documentation	Information Services, public relations, Media studies, Publishing, Journalism

Linguistics and Classics	Linguistics, Literature, English studies, Ancient language studies, Celtic studies, Latin studies, Classical Greek studies, Classics
European Languages and Literature	French studies, German studies, Italian studies, Spanish studies, Portuguese studies, Scandinavian studies, Russian and East European Studies, European Studies
Other Languages and Literature	Chinese studies, Japanese studies, South Asian studies, Asian studies, African studies, Modern Middle Eastern studies, American studies, Australasian studies
Historical and Philosophical Studies	History by period, History by area, History by topic, Archaeology, Philosophy, Theology and religious studies, Heritage studies
Creative Arts and Design	Fine art, Design studies, Music, Drama, Dance, Cinematics and photography, Crafts, Imaginative writing
Education	Teacher training, research and study skills in education, academic studies in education
Combined courses and others not coded	Combined or unknown subject area

For existing loan borrowers this information comes from SLC administrative data, with some adjustments made to course lengths for those students still on courses using HESA data to simulate some dropping out or changing the length of their course in the future. For those still on courses, future loan amounts are estimated to be the same as their most recent year of loans, uprated by forecast RPIX where appropriate. Some adjustments are also made based on historical SLC data to allow for medical students receiving reduced loan amounts in the 5th and 6th years of their courses and for some students being sandwich students that receive different loan amounts in their placement year.

Some historical loan borrowers are chosen at random to start new courses in future years for which they take out student loans (e.g. a graduate may subsequently take a PGCE course for which they can receive a further loan), while the characteristics of all other loan borrowers starting on courses in future years are created by choosing borrowers at random from the most recent historical year of entrants. The number of entrants assumed to start courses each year for which they receive student loans is estimated by applying the annual growth rates from the student entrant numbers in the DfE student numbers model to the number of borrowers in the most recent year of entrants in the SLC data.

Where a new policy is being introduced and no information is available on historical loan borrowers' characteristics, the distribution of characteristics for future loan borrowers are estimated based on historical HESA data for students on the courses for which loans will be available, with average loan amounts assumed for each borrower based on the DfE student loan outlay model.

Earnings forecasts

The part of the student loan repayment model that forecasts earnings is known as the earnings model. The earnings model estimates earnings and earnings status for each individual for 43 years. This takes into account the different repayment periods of different loan plan types.

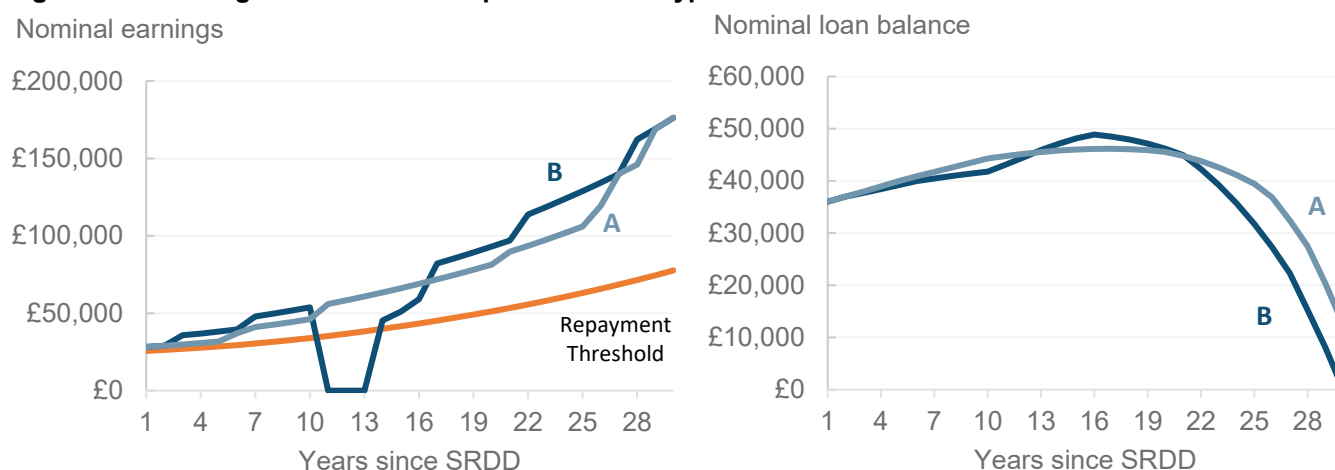

The earnings model forecasts an individual's earnings each year in a two step process. The model estimates whether an individual will be in employment or not, and then, for those in employment, estimates annual earnings. By repeating these steps over subsequent years one by one an earnings path is generated for each individual.

Probabilities of employment and levels of annual earnings are estimated using equations which take into account current and prior characteristics of the individual, such as age, gender and employment history. Earnings estimates are adjusted to align with the earnings distribution, split by age and gender, of the Labour Force Survey and results are produced in 2014-15 earnings values before being converted into nominal values using an index made up of ONS Average Weekly Earnings estimates for historical years and OBR average earnings growth forecasts for future years.

An estimate of the earnings path of loan borrowers is necessary in order to estimate a borrower's repayments across their repayment term. As loans generate interest throughout their repayment period the path of an individual's earnings, rather than their total earnings over the repayment period, has a significant effect on the amount of the loan the borrower will repay.

Figure 4.3 depicts two hypothetical earnings paths, A and B, for a loan borrower with an SRDD of 2019 and a nominal loan balance at their SRDD of c. £35,000. In both cases the individual has the same total nominal earnings over the 30 year repayment period however in scenario B the loan is completely repaid, whereas in scenario A part of the loan (c. £12,000 nominal loan balance) is written off.

Figure 4.3: Earning and loan balance paths for two hypothetical loan borrowers A and B

The equations and earnings distributions used in the earnings model are derived from three main data sources:

- Student Loans Company (SLC) administrative data from 1998 to 2014
- British Household Panel Survey (BHPS) from 1991 to 2009
- Labour Force Survey (LFS) from 2001 to 2014

Administrative data from the SLC is used to understand earnings of recent graduates; who tend to have lower wages and lower employment rates than the average graduate found in survey data. The SLC data includes earnings and employment status in each tax year following a borrower's SRDD as well as characteristics of the borrower, such as subject of study, provider and course level. This is used to build regression models estimating the earnings and employment status of graduates in their first three years past SRDD, and to estimate the earnings distributions of recent graduates.

SLC data does not, however, include the earnings of those who have fully repaid their loan and therefore, once high earners start to repay their loans in full, it provides a biased picture of the earnings of the graduate population. A different data source is needed on which to base estimates of earnings later in a borrower's career. We use the BHPS for this purpose.

The BHPS⁷ is a longitudinal study, over up to 18 years, of a representative sample of around 10,000 individuals. It interviewed each adult in a household and included questions on earnings and qualification level. The data on GB residents from this survey is used to construct regression models for forecasting employment status and earnings and mapping the earnings distribution of non-recent graduates.

Due to differences in survey design whilst the BHPS gives a better indication of individual earnings trends over many years, the LFS is a more reliable source of actual earnings of an individual given their age and

⁷ Further information on the BHPS can be found on the University of Essex website: <https://www.iser.essex.ac.uk/bhps>

gender. The final earnings estimates from the model are aligned with an earnings distribution created using aggregated LFS data.

The earnings model also uses two other data sources for adjustments to the model. The Average Weekly Earnings (AWE) index, published by the ONS, is used to re-baseline survey and SLC data to earnings in 2014-15 financial year terms. The Destination of Leavers from Higher Education (DLHE) is used to estimate the impact of age at SRDD on a loan borrower's earning profile, this is to take into account that a recent graduate aged 30 for example is unlikely to have the same earnings or earnings growth as a borrower aged 30 who graduated aged 22.

Estimates of earnings are likely to be influenced by the level of qualification of individuals. As such, the earnings model is split into four sub-models, based on the qualification level of the borrower:

- Sub degree qualifiers
- First degree qualifiers
- PGCE qualifiers
- Dropouts

To reflect the different qualification levels, each sub-model uses a different subset of the BHPS and SLC data when deriving equations or earnings distributions, as shown in table 4.4.

Table 4.4: Subsets of SLC and BHPS data used for modelling each subpopulation of borrowers

Subpopulation	SLC data subset	BHPS data subset: based on highest qualification
Sub-degree qualifiers	Sub-degree qualifiers	HND/HNC or equivalent
First degree qualifiers	First degree qualifiers and PGCE dropouts	First or higher degree
PGCE qualifiers	PGCE qualifiers	First or higher degree
Dropouts	Dropouts from sub and first degrees	A levels or equivalent.

Forecasting employment status

Prior to estimating and individuals earnings, the model assigns borrowers to one of four employment states:

- Employed
- Non-employed
- Migrated
- Other zero (inactive or not repaying for a reason other than migration or non-employment, such as an incomplete tax return or inconsistent data)

The probability of being in each of the four states is conditional on the borrower's characteristics, prior employment states and prior earnings.

SLC provides earnings and migration data for those borrowers already past their SRDD. Where the employment state of a borrower can be derived from SLC data this is used within the earnings model. Up to three years of prior employment states may be used when estimating future employment states.

For those yet to pass their SRDD an initial employment state post SRDD is also estimated.

SLC data is used to build binary logistic regression models predicting the likely employment state of borrowers. These regression models produce the log odds of being in each employment state, which is

then transformed into a probability. The probability of being in each of the states is then scaled so that the sum of the four states is equal to 1.

In the first year post SRDD, probabilities of being in each of the four states are based solely on the characteristics of the borrower – for example, an EU borrower will have a much higher chance of emigrating compared to a UK borrower. In subsequent years, prior employment state and earnings are also considered when estimating employment state.

A borrower is likely to be assigned to the state corresponding to the highest probability, however to take into account the variation that cannot be explained through the borrower's characteristics random variation is also included in the employment states. This perturbs some borrowers away from the expected employment state.

If a borrower is in the migrated or other zero state then an additional logistic regression model is run to determine whether the borrower is also employed or non-employed.

Example case

Borrower characteristics: England-domiciled, female, age 22 at SRDD, SRDD 2018, studying business & administrative studies, first degree, at a university within the University Alliance HEI grouping.

Given the borrower's characteristics, the regression models for employment estimate in their first year post SRDD:

Probability of migrating = 1%

Probability of other zero state = 2%

Probability of non-employment = 9%

Probability of employment = 88%

Based on these probabilities the model then randomly assigns the borrower an employment state. In this case, the borrower has an 88% chance of being assigned to the employed state.

Forecasting earnings

Once the model has assigned an individual to an employment state it moves on to estimating earnings. Earnings are estimated for borrowers who are employed, including those who are employed but also migrated or in the other zero state. Borrowers who are predicted to have a non-employed state are estimated to have zero earnings in that forecast year.

Earnings are estimated through linear regression models using maximum likelihood estimation (general linear models). The regression models use a square-root transformation of earnings as this creates a more normal distribution of earnings compared to the natural log transformation. The outputs from the regression models can be squared to provide the actual earnings estimate. The earnings regression models also contain a stochastic element to perturb an individual away from the expected earnings given their prior employment history; this ensures the full distribution of earnings across the population is captured in the model.

To take into account the different earnings profiles of men and women the model uses different regression models for each gender. Lookup tables are then used to adjust estimates to reflect the distribution of earnings exhibited in the LFS.

Borrowers with no earnings history

For borrowers with no earnings history the first three years of estimated earnings after their SRDD are estimated using regression models based on SLC data. Each of the initial three years after SRDD uses different regressions models to estimate future earnings; this enables the model to take into account the additional information, in the form of prior earnings and employment status, available as the borrower ages.

In the first year after a borrower's SRDD, earnings are based on the borrower's characteristics, such as HEI group, domicile, age and SRDD.

In the second and third years after SRDD, different regression models are used for each gender for those with:

- no earnings in the previous year
- low earnings in the previous year (less than £10,000 in 2014-15 values)
- average earnings in the previous year (between £10,000 and £30,000 in 2014-15 values)
- high earnings in the previous year (over £30,000 in 2014-15 values)

Regression models for men with low prior earnings are highly dependent on the borrower's age, periods of prior unemployment and previous earnings; female low earnings are also dependent on provider group.

From the fourth year past SRDD onwards earnings are estimated using BHPS based regression models

Borrowers with an earnings history

Where some earnings history is provided by SLC this is used in forecasting future earnings.

If the borrower is one or two years past their SRDD then SLC based regression models will be used to estimate unknown earnings until their third year past SRDD, after which BHPS based regression models are used.

If three years of earnings history is known the borrower's first estimated earnings will be based on BHPS based regression models, in the same manner as estimating the fourth year of earnings for new earners.

Long-term earnings forecasts

Long-term earnings (those from the fourth year after SRDD onwards) are estimated using BHPS based regression models, adjusted to follow the LFS earnings distribution. The regression models are based on both borrowers' characteristics and their earnings in the previous three years.

Estimates of earnings often differ between surveys, due to differing survey aims and populations. As such the data from the BHPS on graduate earnings follows a different distribution to that in the LFS. For example, the median earnings of a 25-year-old female graduate in 2014-15 values are £23,951 according to the aggregated LFS data⁸ (2001-2014), but this is equivalent to only the 44th percentile in BHPS data (when aggregated from 1990-2009).

As such, the BHPS based earnings estimates are corrected to follow the LFS earnings distribution. This adjustment is accomplished by considering the percentile of the earnings estimated by the BHPS based regression models for a graduate of that age and gender and finding the equivalent earnings for the same person at the same percentile in the LFS data. For example, the BHPS regression model may estimate a female graduate, age 25, to have median earnings (for her age and gender) of £25,337 in 2014-15 values. However, we output the equivalent median earnings for a 25-year-old female graduate in the LFS data (£23,951 in 2014-15 values), rather than the BHPS based estimate.

Similarly, earnings estimates often differ between survey and administrative sources, for example because high earners are often difficult to survey, proxies may answer questions and individuals may not wish to disclose their exact salary. As such, a similar adjustment must be made to earnings known from SLC data and/or earnings estimated in the first three years of employment to avoid a discontinuity in earnings estimates when switching the data source for regression models between the third year of earnings, based on SLC data, and the fourth year of earnings, based on BHPS data.

This adjustment between survey and administrative data based models is very similar to the process above for converting from BHPS to LFS data. We output the SLC earnings estimates for the first three years past

⁸ Comparisons of LFS data to administrative data on earnings from the Annual Survey of Hours and Earnings (ASHE) have shown that whilst the distribution of earnings in the LFS is noisier than in ASHE the profile is very similar when considering the whole population (Nanton & Rowling, 2017).

SRDD, but we use the equivalent BHPS estimates (the earnings for a person of the same age and gender at the same percentile in the BHPS earnings distribution) when we need estimates of prior earnings within the BHPS based earnings models.

Age at graduation

The earnings profile of a new graduate aged 22 and a new graduate aged 45 may be quite different; typical borrowers may have more graduate level work experience than mature borrowers do once they reach the same age.

We cannot take account of this in the regression models derived from BHPS data as we do not always know the age at which a respondent graduated. Instead we take account of the impact of the age of the borrower at SRDD by deriving a second earnings forecast using a more typical age (21 or 22 depending on degree type), and a weighted average of the two earnings forecasts is taken. The weights initially result in more weight being given to the typical age earnings forecast and more weight to the actual age forecast as the borrower gains more experience (approximated by the number of years since SRDD). Weights are derived from DLHE data on the earnings of borrowers 6 months and 42 months after graduation.

As the BHPS regression models make use of prior earnings, typical age equivalents of actual or forecast earnings in the first three years past SRDD are also needed.

SLC provides tables of the earnings distribution by age and gender of borrower for each of the first three years past SRDD. These are used to find the percentile for the borrower's earnings in the first three years past SRDD. The BHPS earnings for a borrower of the same gender but of typical age are then used as prior earnings information in the typical age BHPS based earnings estimates.

For graduates with more than three years of prior earnings data, i.e. where the prior earnings data from SLC refers to their fourth year past SRDD or later, the age adjustment does not use the SLC lookup tables. Instead, the LFS percentile of their earnings is used when finding the equivalent BHPS earnings for a typical age borrower.

Retirement

For some borrowers the 43 years of forecast earnings may include a period of retirement. Borrowers are assumed to retire at 65, after this age their earnings will be modelled as zero for the remainder of the forecast years.

During the time period over which the BHPS data was collected, State Pension Age for men was 65. As such, we have very little data on the employment habits and earnings paths of individuals who remain employed after this age, and no information from the BHPS on the impact of raising State Pension Age. Given the lack of reliable data and that most borrowers will have reached the end of their repayment term before age 65, we have chosen to fix the retirement age in the model at age 65.

Repayment frictions

Borrowers make repayments based on the income for which they are liable to pay National Insurance Contributions. Each year they are required to repay a percentage of their annual income that is above the annual repayment threshold. However, the earnings forecasts are an idealised version of an individual's earnings over the course of the year, as they do not take into account various factors that may affect the amount a student repays compared to what would be expected based on their annual earnings. These differences between the amount borrowers actually repay and the amount they would be expected to are known as 'repayment frictions'. Some of the factors which create frictions are:

- the difference between gross income and income liable for National Insurance Contributions;
- only being employed for part of the year;
- having multiple employments;
- earnings changing mid-year; and,

- technical issues such as National Insurance numbers not matching their student loan account to their HMRC record, or the borrower not having a National Insurance number.

Part-year employment and mid-year earnings changes can cause frictions for the same reason. For employees, student loan repayments are deducted each pay period, e.g. monthly. The annual threshold is divided by the number of payments the employee would expect to receive over the year and repayments calculated each pay period on this basis. This can result in an employee paying more over the course of the year than would be expected, for example if they earn most of their annual income over a few months they would make repayments each month as if they were going to earn that same amount each month for the rest of the year, even though they may subsequently earn less than the repayment threshold in other months.

Multiple employments can on the other hand reduce the amount repaid on student loans, as the borrower would need to exceed the earnings threshold in each job to make repayments on their loan. As such, some individuals may have an annual income, from multiple jobs, above the repayment threshold, but make no repayments as they are not over the earnings threshold in either employment.

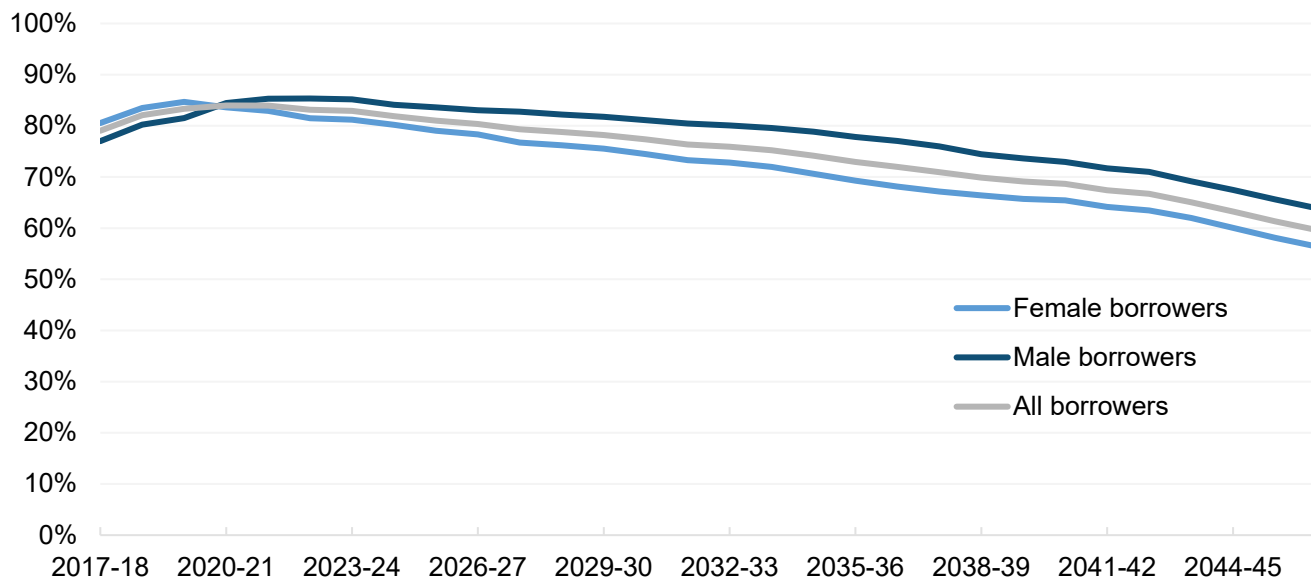

To correct for these frictions, the model applies a correction to the estimated earnings of some borrowers to increase or decrease the forecast earnings of the borrower, so that they make repayments as if they had this altered earnings amount. The proportion of borrowers whose repayments are altered and the sizes of the changes are based on the differences seen between earnings and repayments in historic SLC data, and vary based on their earnings amount and the length of time since their SRDD.

Earnings forecast outputs

At this point in the modelling we have generated annual equivalent earnings for those in employment in the UK at an individual level. These can be aggregated to provide insights to the earnings forecasts underlying the repayment forecasts.

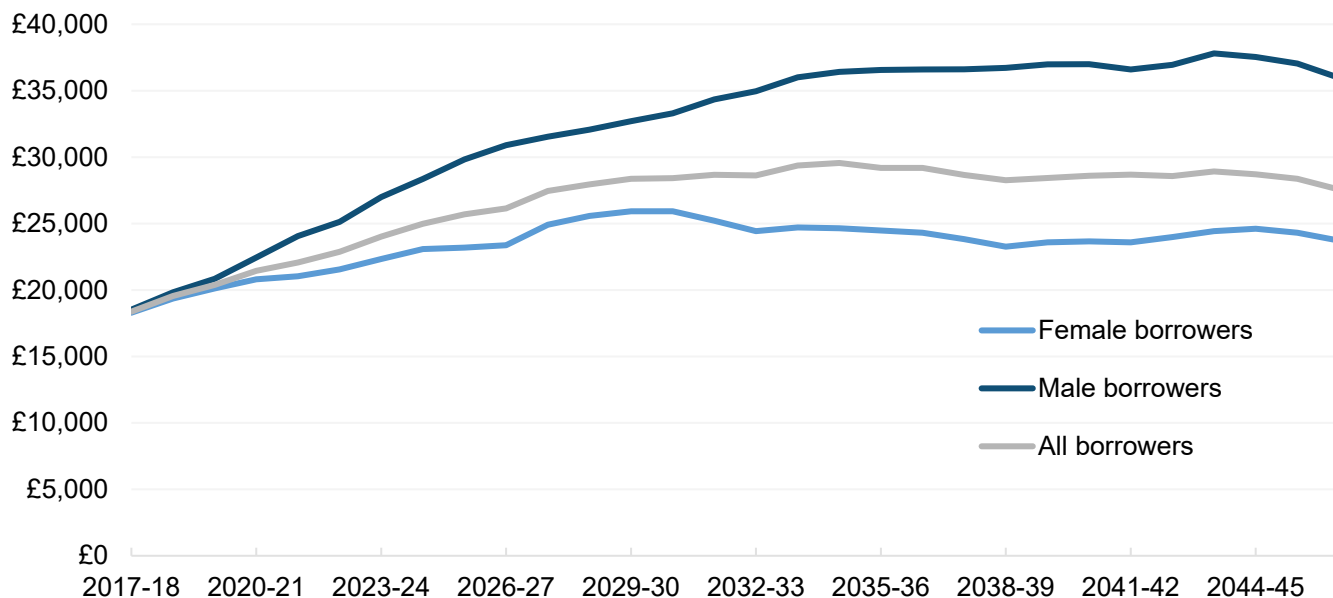

For those borrowers with an SRDD of 2017 we forecast the proportion of borrowers employed (in the UK) over 30 years, in Figure 4.4. We find that employment rates peak in the 4th year past SRDD and that during the first three years after SRDD female borrowers are forecast to have marginally higher employment rates than male borrowers. Employment rates across all borrowers decrease after the 4th year past SRDD, driven initially by declining female employment. The gap between male and female employment rates increases over the following 10 years to a long-term average of 8 percentage points. The model assumes that the employment decision of individuals in the future will be similar to historic ones derived from survey data and SLC administrative data. This includes historic patterns for employment by gender, which will not necessarily be the case, especially in the long term.

Figure 4.4: Forecast proportion of borrowers in employment in the UK by gender: 2017 SRDD cohort
Financial years 2017-18 to 2046-47

For those with an SRDD of 2017 who are forecast to be employed, Figure 4.5 shows the median forecast earnings each year in 2014-15 values. Forecast median earnings for the first year past SRDD are £18,500 in 2014-15 values (equivalent to £20,000 in nominal terms in 2017-18) with little difference between male and female earnings. Median earnings for male and female borrowers diverge over the loan term growing to an average gap of £13,000 in 2014-15 earnings values over the last 10 years of the loan term. The model assumes that the earnings paths of individuals in the future will be similar to historic ones derived from survey data and SLC administrative data. This includes historic patterns for different distributions of earnings by gender, which will not necessarily be the case, especially in the long term.

Figure 4.5: Forecast median annual earnings of those in employment by gender: 2017 SRDD cohort
Financial years 2017-18 to 2046-47, earnings in 2014-15 earnings values

The distribution of forecast earnings by gender is further broken down in Figures 4.6 and 4.7. The distribution of female earnings is closely grouped around the median, with 50% of female borrowers earning within £10,000 of median earnings. In comparison the male earnings distribution is more disperse,

with the top decile of male borrowers earning over the 30 year loan term on average 1.6 times that of female borrowers in the top decile.

Figure 4.6: Forecast distribution of annual earnings of female borrowers in employment: 2017 SRDD cohort
Financial years 2017-18 to 2046-47, earnings in 2014-15 earnings values

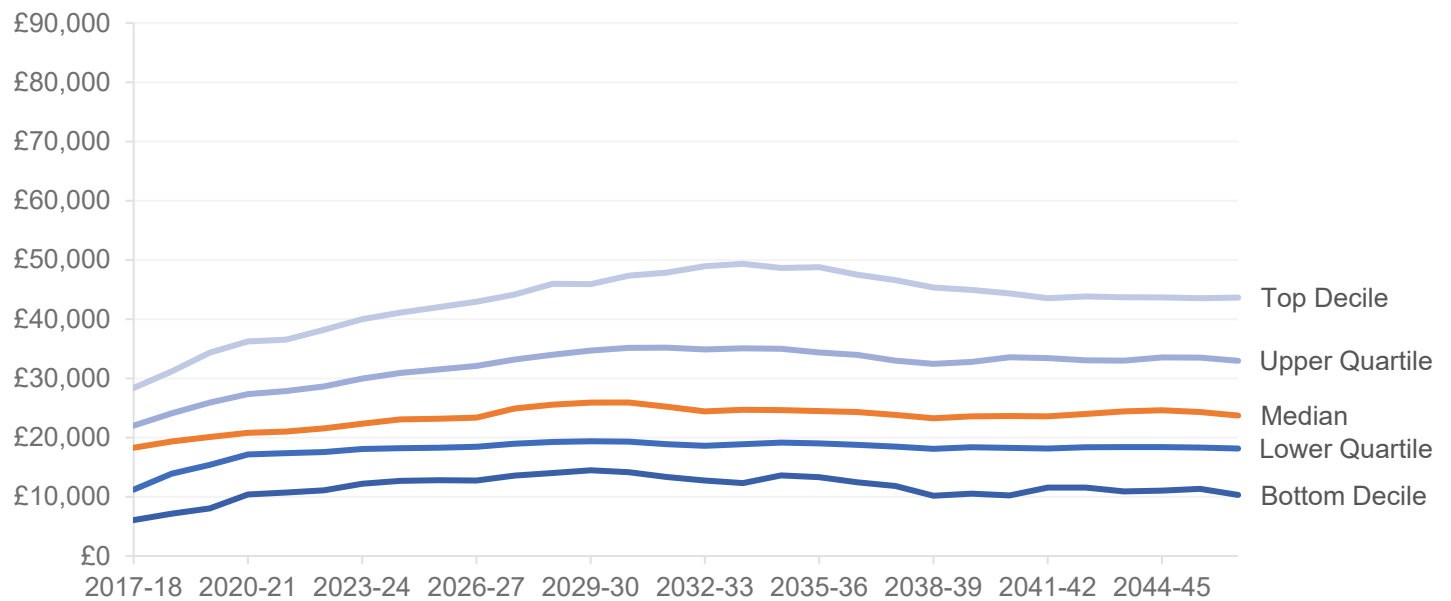

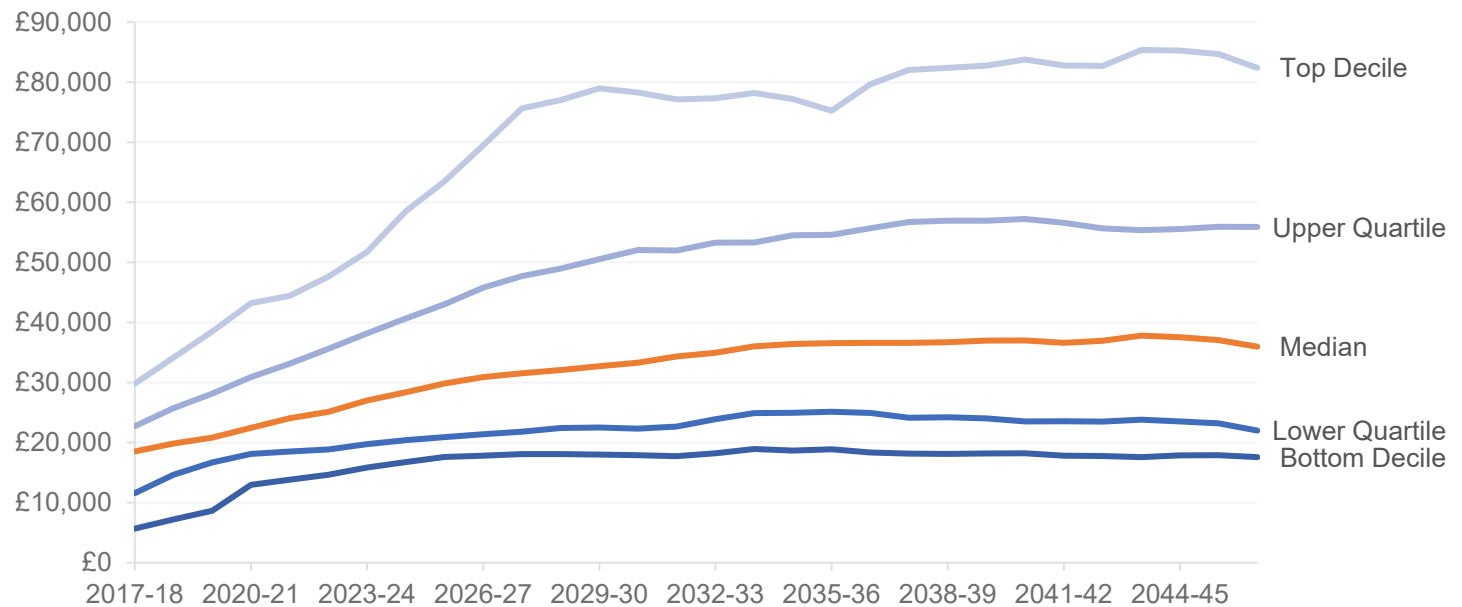

Figure 4.7: Forecast distribution of annual earnings of male borrowers in employment: 2017 SRDD cohort
Financial years 2017-18 to 2046-47, earnings in 2014-15 earnings values

Investment income

A borrower is expected to declare any investment income above £2,500 to HMRC, and this will be added to their overall earnings figure for the purpose of student loan repayments. The model calculates a probability that a borrower will earn investment income based on their age, labour income, gender and whether they declared investment income in the previous year (based on logistic regression models generated from BHPS data). Based on these probabilities some borrowers are selected to have investment income each year.

Then an investment income amount is generated using a linear regression model based on the same set of characteristics, which is added to their labour income. If the model determines that the borrower has

earned an income from their investments but it amounts to less than £2,500, then this is treated as zero investment income as the borrower would not be expected to declare this to HMRC.

Mortality

ICR loans can be cancelled prior to the end of the repayment term if the borrower dies. The probability of death in a given year is based on the borrower's age and gender, and is derived from ONS life tables and SLC data. SLC data shows lower write-off levels than would be expected from ONS mortality rates, most likely reflecting that graduates have lower mortality rates than non-graduates of the same age. But the historic SLC data has little coverage of student loan borrowers aged above their mid-30s, so a weighted average of the two sets of mortality rates is taken that gives a high weighting to the SLC data at younger ages and to ONS data at older ages.

There are several reasons other than death why a loan may be written off before the end of a borrower's repayment term, such as if they become disabled to an extent that they will be permanently unable to work. However, the level of these write-offs is comparatively small so they are not included in the model.

Repayments made directly to SLC

In addition to obligatory repayments collected through the UK tax system, repayments can also be paid directly to the SLC. These fall into three main categories:

- Voluntary repayments (prepayments) – These are early repayments made by the individual in addition to their obligatory repayments.
- Payments from overseas – Repayments from borrowers situated overseas cannot be collected through the tax system. Overseas borrowers make obligatory repayments direct to the SLC based on their income and the earnings threshold for their country of residence.
- Direct debits – In the last couple of years of payment the SLC offer the borrower the opportunity to repay the rest of their loan through a direct debit to prevent overpayment.

The probability of a borrower making a voluntary repayment each year is generated from a logistic regression model based on SLC administrative data. Voluntary repayments are particularly dependent on the magnitude of the debt outstanding and the number of years into the repayment period, as well as whether a borrower has previously made a voluntary repayment. In addition, the regression model also takes into account borrowers' age, gender, domicile, course level, subject group and provider group. The majority of voluntary repayments come from borrowers with low amounts of debt in the first few years of repayment. If a borrower is due to make a voluntary repayment in the model, a percentage of the debt outstanding is paid as a direct repayment. This percentage is derived at random from a distribution based on the size of the borrower's remaining loan and the number of years since their SRDD.

Borrowers with an employment status of migrated can make overseas repayments. The probability of a migrated borrower making an overseas repayment each year is generated from a logistic regression models based on SLC administrative data. The regression model takes into account the borrower's age, gender, domicile, course level, subject group, provider group and how many years into their repayment period they are. The size of the repayment is selected at random from a distribution of repayment amounts based on the number of years since the borrower's SRDD.

In the model, borrowers are given a probability of making direct debit repayments rather than obligatory repayments if they repaid more than half of their remaining loan balance in the previous year. If selected to make direct debit repayments a borrower will repay half of their remaining loan balance in the first year of making them and the remainder of their balance in the second year.

Postgraduate loan borrowers

As they are new loan products, no historic data on postgraduate loan borrowers is available. In addition, information on postgraduate earnings and behaviours from survey data is limited, as in population surveys the proportion of the survey respondents that have postgraduate degrees is very small. Therefore, the

student loan repayment model generates employment and earnings forecasts for postgraduate loan borrowers using the same earnings model as for first degree students with the same characteristics, to which it then applies a fixed uplift to earnings in all years to account for the higher earnings postgraduates are expected to have.

For master's borrowers an earnings uplift of 8.9% is applied for male borrowers and 10.3% for female borrowers. This is based on research that estimated this to be the average marginal earnings gain for master's students on top of their undergraduate degree (Conlon & Patrignani, 2011). For doctoral students an earnings uplift of 8.0% is applied for male borrowers and 6.0% for female borrowers. These uplifts are based on results for doctoral students from the same research, but have been adjusted down to reflect the higher undergraduate earnings expected of those who take up doctoral studies, based on factors such as subject of study and HEI group. These factors were not accounted for in the research due to the available sample size. These uplifts for master's and doctoral students are not directly comparable, as the other factors will also affect the average earnings for each course level.

As there is no administrative information available for them as yet, postgraduate loan borrowers are assumed to have similar behaviours as an equivalent first degree student for factors such as such as voluntary repayments, overseas repayments, mortality and investment income.

Loan borrowers on part-time courses

We do not forecast earnings for borrowers whilst they are undertaking a course, this includes part-time loan borrowers studying for longer than 4 years who have an SRDD in the fifth April after the start of their course, even if they are still studying. Similarly, we do not take into account the impact of earnings prior to taking up a university course on earnings on completion. As such, earnings estimates for part time loan borrowers may be lower than actuals on entry into the labour market. However, we do not expect this impact to be long lasting and modelled earnings for part-time loan borrowers will tend towards those of full time loan borrowers as they move further through their career.

Repayment amounts and debt outstanding

Once annual earnings (including any investment income) are calculated and non-employment, migration, frictions and mortality taken into account, the obligatory repayments are calculated according to the deterministic repayment rules for that year. All obligatory, voluntary, overseas or direct debit repayments that the borrower makes each year are summed together, up to a maximum of the borrower's remaining loan balance. Borrowers are assumed to stop repaying their loan once their loan balance reaches zero; the model does not model borrowers making overpayments or receiving refunds after overpaying.

To calculate the size of a borrower's loan balance, borrowers are given annual outlay amounts while on their course based on the distribution of outlay amounts of historical borrowers in the SLC data, uprated in line with forecast RPIX depending on the appropriate loan policy. Capitalised interest is accumulated each year and added to the size of the borrower's debt, while any repayments are subtracted from it. The size of the borrower's debt is calculated on this basis each year until they either fully repay their loan or until their loan is cancelled, either due to mortality or because they reached the end of their repayment term.

In reality, repayments are generally made on a monthly or weekly basis, but as a simplification in the model all repayments (obligatory and direct) are assumed to be made in the middle of the financial year. Interest for the first half of the year is added to the debt outstanding at the start of the year before repayments are made, then the interest for the rest of the year is added after they have been deducted. If a borrower's loan is cancelled this is assumed to happen at the end of the financial year, as this is the point when cancellations will occur at the end of a borrower's repayment term, which are expected to account for the large majority of cancellations.

Interest rates each year are calculated from RPI, the Bank of England base rate (Plan 1 only) and borrowers' income (Plan 2 only) in line with the appropriate policy. RPI and Bank of England base rate figures are based on OBR forecasts. The interest rates for each part of the year are calculated and then combined into an annual average that is used across the financial year. For all three loan plans the RPI figure used in calculating interest rates changes each September to the March RPI figure published by

ONS in the same year, but as OBR only publishes quarterly forecasts (and in the long run only annual forecasts) the model uses the forecast for the equivalent January to March quarter in the short run, and the annual figure for the same financial year in the long run. The Plan 1 interest rate can potentially vary each month between RPI and the base rate +1%, so to simulate this the OBR's quarterly forecasts for the base rate are used and compared to the RPI figure each quarter (twice in the Jul-Sep quarter when the RPI figure that is used can change).

Population totals

Forecasts for individual loan borrowers are aggregated together to estimate totals for the whole student loan borrower population. Rather than making estimates for the whole population of loan borrowers, to make the model more efficient, forecasts are only made for a sample of loan borrowers, with weightings applied to these borrowers' results to estimate totals for the whole population.

A simple random sample of 200,000 borrowers is used for each loan product, covering entrants from the first year that the loan product was introduced up to entrants in academic year 2022/23 (excluding those that have already finished repaying their loans or had them cancelled). This amounts to a 7% sample for Plan 1 loan borrowers, a 5% sample for Plan 2 full-time borrowers, a 36% sample for Plan 2 part-time borrowers and a 51% sample for master's loan borrowers. A 100% sample is used for doctoral loan borrowers since fewer than 200,000 entrants are expected over this period.

The scaling used to increase the sample results to population totals is weighted based on several variables to reduce the sampling bias in the model. The variables used in the weighting are course start year, SRDD, domicile, gender, course level, subject group, the borrower's write-off rule and whether the loan has been sold (Plan 1 only).

The Resource Accounting and Budgeting (RAB) charge and the stock charge

The RAB and stock charges are the estimated cost to Government of providing a subsidy for the student finance system. They are the proportion of loan outlay (the RAB charge) and of the total outstanding loan book (the stock charge) that are expected to not be repaid when future repayments are valued in present terms.

To calculate the RAB charge the total outlay in a given year is added up and compared to the total net present value (NPV) of the repayments that are anticipated in connection with this same outlay. The RAB charge is calculated as

$$\text{RAB charge} = \left(1 - \frac{\text{NPV of repayments in respect of outlay}}{\text{value of outlay}} \right) \times 100\%$$

Similarly, the stock charge is calculated by summing all outstanding loan balances at the start of the year and comparing this to the total net present value (NPV) of the repayments that are anticipated in connection with these loans. The stock charge is calculated as

$$\text{Stock charge} = \left(1 - \frac{\text{NPV of repayments in respect of outstanding loan balances}}{\text{face value of outstanding loan balances}} \right) \times 100\%$$

The NPV of future repayments is calculated by discounting all future repayments at a rate of RPI+0.7% per year to the same point in time as the loan outlay or loan balance. This is the discount rate for financial instruments set by HM Treasury (HMT)⁹ and is intended to reflect of the cost of Government borrowing.

Student loans are valued in DfE's annual accounts in line with International Accounting Standard 39, under which where future cash flows are discounted to measure the fair value of a financial asset, this should be done using the higher of the rate intrinsic to the financial instrument or the Her Majesty's Treasury (HMT) discount rate. For student loans the intrinsic rate would be the discount rate that gave a RAB or stock charge of 0%, so the HMT discount rate is used provided the RAB or stock charge is greater than 0%.

⁹ [Discount rates for post-employment benefits, general provisions and financial instruments: Announcement of rates](#) - HM Treasury, December 2015.

Should the HMT discount rate result in a RAB charge or stock charge calculation giving a negative value then the intrinsic rate is used instead, meaning that that RAB charge or stock charge will take a value of 0%.

In the model, RAB charges are calculated for the loan book as a whole by first calculating the NPV of individual borrowers' repayments, then for each year aggregating these together across all borrowers and comparing them to their total loan outlay in that year. Stock charges are calculated in the same way, aggregating the NPV of individual's repayments before aggregating them to a population total and comparing this to the face value of the loan book at that point in time. Where a borrower has more than one year of outlay or has both future loan outlay and an existing loan balance that will be included in the stock charge, future repayments are allocated between each year of their loan outlay and their existing loan balance in proportion to the relative balances of each loan when valued at the same point in time (i.e. talking into account interest accrued on the earlier loan balances).

A RAB charge is no longer produced for Plan 1 loans as very few Plan 1 students are still receiving loans. It is not possible to produce a reliable RAB charge as the small numbers mean there would be a high level of uncertainty around any forecasts, particularly as these may be an atypical group of students that will not follow the same future earnings distribution as the overall population.

Data quality

Producing forecasts is inherently uncertain and in particular, there is a significant level of uncertainty in the 30-40 years of earnings and repayment forecasts required to produce the RAB and stock charges. These are very dependent on the data sources, modelling techniques and assumptions used in the model. In particular, the model assumes that the distribution of future earnings paths will be similar to historic ones derived from survey data and SLC administrative data, which will not necessarily be the case, particularly in the long term.

The model is dependent on the OBR macroeconomic forecasts that it uses to uprate earnings, calculate interest rates and repayment thresholds, and to discount future repayments to present values. Any significant changes to the economy from these forecasts could affect the repayments that will be made on student loans.

Table 7 in the Excel tables accompanying this publication demonstrates the sensitivity of the Plan 1 stock charge and the Plan 2 full-time higher education RAB charge to the OBR forecasts. The variations shown are larger than the changes that would typically be seen in OBR's forecasts from one year to the next. For Plan 2 the table also shows the impact that varying some of the policy parameters would have. The Government is currently carrying out a [review of post-18 education and funding](#), which could potentially recommend changes to the student loan system that would affect these forecasts.

The model uses SLC administrative data to determine borrower characteristics, loan amounts, earnings in the first three years of their repayment term and repayments made directly to SLC. Being from an administrative source the historical SLC data should be broadly accurate, although the earnings and direct repayment forecasts rely on future borrowers having similar behaviours to historic borrowers. SLC published data quality guidelines on the following webpage: <https://www.slc.co.uk/official-statistics/guide-to-our-statistics/compliance.aspx>

SLC administrative data is used within the model to produce earnings forecasts in the first three years after a borrower's SRDD; the forecasts beyond this do not explicitly use the additional details about borrowers' course characteristics that the SLC data provides. This could affect the forecasts if different groups of borrowers with similar earnings in the first three years after SRDD in reality have quite different subsequent earnings paths, as in subsequent years the model would forecast them as having a similar distribution of earnings. This also means that it is not possible to produce forecasts for subgroups of loan borrowers, for example based on subject or provider groups.

Where new loan products are being introduced, the forecasts are more uncertain as there is less historical information available on which to base forecasts and more uncertainty about what student behaviours will be in response to the policy. This is particularly the case for the two postgraduate loan products, for which

the earnings forecasts are less well developed than for undergraduates and for which there is no historical information about loan borrowers' characteristics and behaviours.

Earnings distributions

The model currently forecasts earnings for borrowers from financial year 2016-17 onwards, as earnings in 2015-16 and earlier are available in the SLC administrative data. It can be difficult to compare earnings forecast by the model to survey or administrative data due to lags in data reporting. Instead, we compare trends in forecast earnings paths to those seen in survey data. We do this by aggregating LFS data from 2006 to 2017 (where earnings have been adjusted to 2014-15 earnings values) and comparing the distribution of earnings for borrowers at various ages to the distribution of earnings produced in the earnings model.

As the LFS only records graduates, rather than student loan borrowers, the raw data is not directly comparable to the borrower population. We would expect borrowers to have slightly lower earnings on average than graduates, as some graduates will not take out a loan and some borrowers will not graduate. We therefore apply a heuristic to the LFS data, through reweighting, to make the LFS graduate population more comparable to the borrower population.

After the heuristic has been applied we can compare the distribution of earnings for male and female Plan 2 borrowers, as in in Figures 4.8 and 4.9. In both male and female distributions, the model estimates agree with the trend in the LFS data. Data on graduates' earnings nearer retirement tend to be quite volatile, as the number of individuals in employment decreases; this inhibits forecasting, however most borrowers will have either repaid their loan by this point or passed the end of their loan term.

Figure 4.8: The distribution of earnings of male Plan 2 borrowers by age over the working lifetime, estimates compared to distribution observed in LFS data.

Annual earnings, 2014-15 earnings values

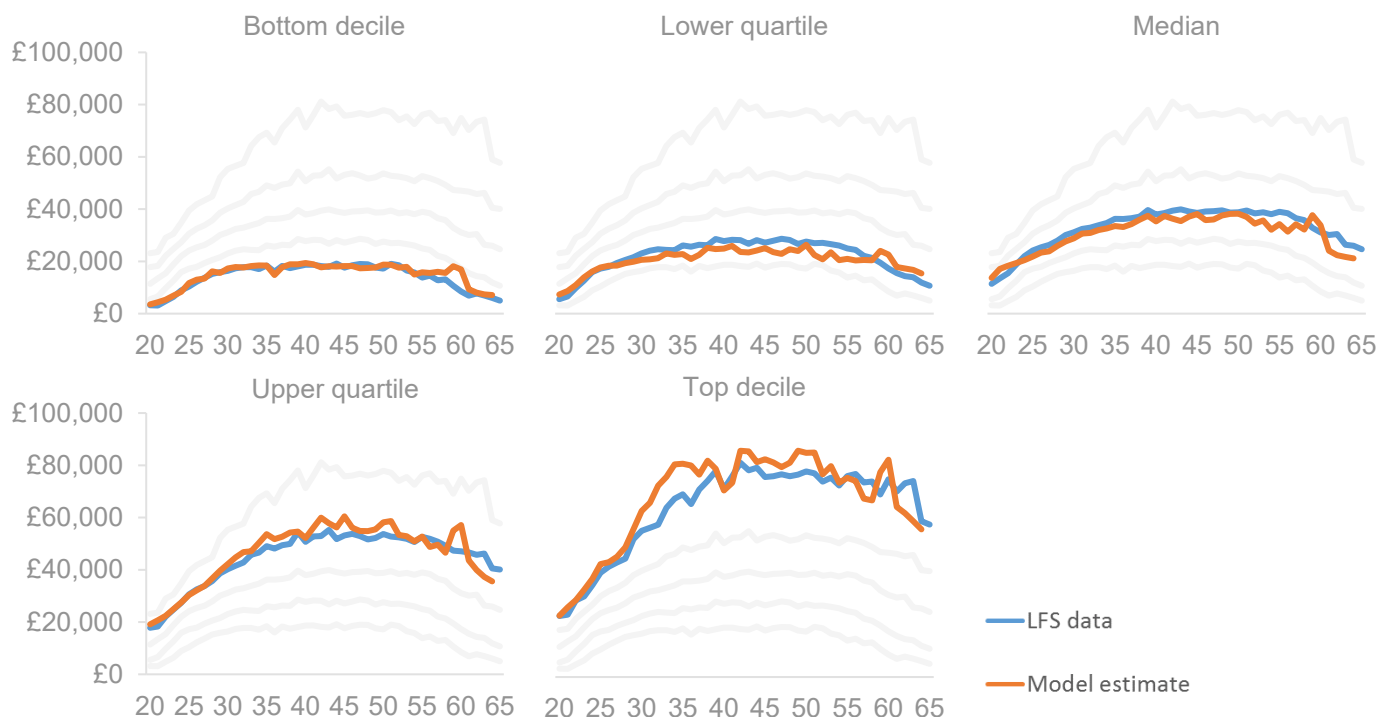

Figure 4.9: The distribution of earnings of female Plan 2 borrowers by age over the working lifetime, estimates compared to distribution observed in LFS data.

Annual earnings, 2014-15 earnings values

Comparison of forecast repayments with actuals

The student loan repayment model is designed to forecast repayments across loan borrowers' repayment terms, but comparisons between forecast repayment totals for individual years and the actual outturn data can give an indication of how well the model is performing. Table 4.5 shows recent outturn figures compared with the forecasts made at the time. New developments are made to the student loan repayment model each year and the data used in it are updated, so forecasts are shown as made at both the start and end of each tax year.

Table 4.5: Forecast and outturn repayments across all higher education loan products

Tax Year	Outturn		Forecast		Difference
	Date	£ million	Date	£ million	
2013-14	30/04/2015	1,590	31/03/2014	1,630	2.5%
			31/03/2015	1,870	6.9%
2014-15	30/04/2016	1,750	31/03/2015	1,920	9.7%
			31/03/2016	2,140	10.9%
2015-16	30/04/2017	1,930	31/03/2016	1,930	0.0%
			31/03/2017	2,320	:
2016-17	30/04/2018	:	31/03/2017	2,250	:
			31/03/2017	2,570	:
2017-18	30/04/2019	:	31/03/2018	2,460	:

These figures include repayments made directly to SLC and PAYE and Self Assessment repayments made via HMRC. Direct repayments are recorded against the year they are received by SLC, HMRC repayments are recorded against the year of the earnings they relate to.

Repayments across all loan products are included in the data. Up to 2015-16 only Plan 1 borrowers were

eligible to make obligatory repayments, though Plan 2 borrowers could make voluntary repayments. From 2016-17 the first Plan 2 borrowers became liable to make obligatory repayments, and the first Plan 3 borrowers will in 2019-20.

Actual outturn data is not known until the April just over a year after the end of the tax year. These data are not completely final as small amounts may still be repaid after this point.

Variances between forecasts and actuals will be due to a range of factors, including:

- Macroeconomic shifts and new data
- Modelling variances and random variation
- Operational factors that result in lower than expected collections.

By the time of the second forecast shown for each year the macroeconomic data for the year will largely be known, so the forecast is less dependent on OBR macroeconomic forecasts. But modelling changes and other data updates will also have occurred so changes between the two forecasts also include other factors.

5. Student numbers model

Introduction

The student numbers model forecasts the growth of full-time undergraduate entrants by UK and EU domicile at English providers eligible for Office for Students (OfS) funding. The forecasts include students who satisfy the following requirements:

- Full-time, undergraduate level study;
- Defined as entrants at a provider;
- UK and EU (non-UK) domiciled;
- Registered at English providers; and,
- Since academic year 2017/18, nursing, midwifery and allied health profession (NMAH) entrants have been part of the main student support system and are included as additional entrants alongside the main forecasts from 2017/18.

The forecasts do not include:

- Part-time students;
- Postgraduate students;
- Students registered at Alternative Providers;
- Further Education students;
- Non-EU domiciled students;
- Students at providers in Wales, Scotland or Northern Ireland; and,
- Continuing students, i.e. those students who have previously been registered at an eligible provider at the same study level.

Further information on the definition of entrants and students eligible for Office for Students funding is available from annual Higher Education Students Early Statistics Survey (HESES) and Higher Education in Further Education Students Survey (HEIFES) survey publications.

The student number forecasts are primarily used by the Office for Budget Responsibility in the Economic and Fiscal Outlook. Further information on historic forecasts and assumptions is available in the OBR's Economic and Fiscal Outlook – March 2018 (Box 4.5 pg.161-162).

Methodology

UK and EU domicile entrants

The model considers UK domicile, EU domicile and nursing, midwifery and allied health professional students in three separate groupings. The UK domicile age groupings are 18-19 year olds and 20-24 year olds, reflecting the differences in trends between these age groups.

For UK domicile students, the forecast uses projections of ONS population estimates, Universities and Colleges Admissions Service (UCAS) application rates and UCAS acceptance rates, as well as judgements about the behavioural response of providers to a declining population of young people.

The growth of these three factors are combined to produce an overall growth rate of UK domicile entrants, weighted by the proportions of 18-19 and 20-24 year olds. The overall growth rate is applied to historic fundable entrant numbers to project future fundable entrants.

The methodology is similar for EU domicile students. However, only UCAS data on applications to English providers, rather than unique applicants, is available and there are no population estimates in the model. The forecasts assume current trends continue and does not anticipate the outcomes of negotiations on the

UK's withdrawal from the European Union. EU domicile entrant numbers are historically volatile, and the data informing entry to English providers is limited. Therefore, the forecasts should be treated with caution.

The HESES-HEIFES survey provides early estimates for the total entrants figures (with no domicile breakdown), which is used to calibrate the forecasts. The Office for Students provide historic fundable entrants (formerly funded by the Higher Education Funding Council for England (HEFCE)), including a UK and EU domicile breakdown.

Nursing, midwifery and allied health professional entrants

As of academic year 2017/18, nursing, midwifery and allied health professional (NMAH) undergraduate students are included as part of the population eligible for Office for Students Funding and therefore part of the main student support system. The estimates determined by the Department for Education are based on Department of Health and Social Care placement funding.

Data quality

The forecasts use published data from ONS, UCAS, the Office for Students and HESA to forecast undergraduate, full-time entrants only.

The ONS publishes data quality guidance¹⁰ on national population projections, which are the primary population forecast used by Government. The short-term principal projections are considered reliable. Note they make no predictions of future political or economic changes that could affect population numbers.

There is uncertainty in applicant and provider behaviours that could affect the model. For instance, it is unclear how universities will react to a declining youth population, or if future applicants will increasingly secure a place through non-main scheme application routes (such as clearing), affecting application and acceptance rates. Additionally, students may withdraw from a course after accepting a place but before they are classed as an entrant. The model assumes no changes the proportions of students withdrawing prior to entering a provider, although this could change in future.

The model relies on forecasts that do not represent the entire eligible population for undergraduate funding. Whilst 18-24 year olds make up the majority of UK domiciled entrants at English higher education providers, changes in other entrant populations eligible for full-time undergraduate funding could affect these forecasts.

Forecasts produced for EU domiciled entrants are particularly uncertain, with EU domiciled entrants figures historically more volatile than UK domiciled entrants. The smaller volumes (than UK domiciled entrants) inherently introduce more uncertainty, and there is no pre-entry data for these groups. Due to the availability of published data, the model uses the number of EU domiciled applications rather than applicants, which increases uncertainty as the average number of applications each applicant makes could change over time. Additionally, future applicant and provider behaviours after the UK's withdrawal from the European Union and in response other external factors are uncertain.

As the NMAH entrants are under a new funding policy the data informing forecasts is especially limited and the estimates should be treated with caution. For the purposes of student loan forecasts, the Department for Education assumes a linear increase each year in the take up of the increased total clinical places funded by the Department of Health and Social Care.

¹⁰ [Office for National Statistics, National population projections](#)

6. Advanced Learner Loans model

Introduction

Advanced Learner Loans (ALLs) are tuition fee loans to help those aged 19+ at the start of their course meet the up-front costs of regulated Further Education (FE) qualifications at Levels 3 (equivalent to 2 A levels) to Level 6 (equivalent to an undergraduate degree) in England. ALLs were introduced in 2013/14 to those aged 24+ and at levels 3-4 following a refocusing of the Adult Education Budget on adults requiring skills and learning to equip them for work, an apprenticeship or further learning.

Following a public consultation in 2014, the extension of ALLs in academic year 2016/17 to those aged 19-23 and to Levels 5-6 has been the programme's most significant change.

The Resource Accounting and Budgeting (RAB) charge is the estimated cost to Government of borrowing to support the ALLs system. The purpose of the DfE ALLs model is to assist in valuing the existing ALLs loan book and to provide forecasts for budgeting purposes.

The RAB charge is an estimate and it is heavily dependent on assumptions around the future income of ALLs borrowers. At present, we have imperfect information about their repayment ability as ALLs are a new product and the first repayment data will be available in summer 2018. The methodology, data sources and assumptions are presented in the section below.

Methodology

The ALLs model is a micro-simulation model. The model creates thousands of simulated borrowers with a variety of characteristics. Each borrower is assigned a debt and their earnings are projected for each of the next 30 years. Then the repayment rules are applied to each borrower to estimate their repayments, individual loan balance and interest for each of the next 30 years. The assumptions used in the simulation model fall into five main sections below:

1. Borrowers' characteristics and their loan details
2. Macroeconomic assumptions: Average Earnings Index (AEI) and Retail Price Index (RPI)
3. Loans policy assumptions
4. Annual income post learning: employment status, income and income distributions
 - 4.1. Labour market status
 - 4.2. Position on income distribution
 - 4.3. Annual income in nominal terms
5. Life events
 - 5.1. Mortality
 - 5.2. Migration
 - 5.3. Permanently unfit for work
 - 5.4. Extending working lives.

1. Borrowers' characteristics and their loan details

Analysis of administrative Student Loans Company (SLC) data informs the input assumptions on the characteristics of borrowers in each academic year, the courses they study and the average loan size they take. The complete list of input parameters are:

- Total number of new borrowers;
- Proportion of borrowers on multiple courses;
- Course type: A levels, Access to HE, Level 3 Diploma, Level 4 Diploma, Level 3 Certificate, Level 4 Certificate and Level 5/Level 6 courses;

- Gender split of borrowers;
- Age distribution: 19-71 by single year of age;
- Course duration in months: 1-24 months;
- Course start month across academic year;
- Average loan size by type of course (A levels, Access to HE, Level 3 Diploma, Level 4 Diploma, Level 3 Certificate, Level 4 Certificate and Level 5/Level 6 courses).

In addition, we use data from the Individualised Learner Record (ILR)¹¹ to estimate the non-completion rates by type of course.

2. Macroeconomic assumptions

The model uses the Office for Budget Responsibility (OBR) assumptions on future average earnings growth (AEI) and RPI projections to calculate future repayment thresholds, interest rates and discount rates for the ALLs. The model also uses the AEI projections to uprate borrowers' future earnings.

3. Loans policy assumptions

Loans are currently available to learners aged 19+ who are studying Level 3 and above qualifications. The loans are repaid at a rate of 9% of pre-tax earnings above the lower repayment threshold according to table 6.1 below.

Table 6.1: ALLs interest rate and repayment thresholds

Lower repayment threshold	£21,000 until 2017/18; £25,000 in 2018/19, then adjusted annually by the AEI (Q1) thereafter.
Higher repayment threshold	£41,000 until 2017/18; £45,000 in 2018/19, then adjusted annually by AEI (Q1) thereafter.
Interest rate	RPI + 3% up to Statutory Repayment Due Date (SRDD); then RPI for borrowers with income below lower repayment thresholds; RPI + 3% for borrowers with income above upper repayment threshold; $RPI + (3\% \times (\text{income} - \text{lower threshold}) / (\text{upper threshold} - \text{lower threshold}))$ for those earning between repayment thresholds.

Borrowers who study Access to HE courses and complete a higher education course have any outstanding ALLs balance written off.

4. Annual income post learning – employment status, income and income distributions

The key assumption in the model is the future annual income of borrowers after finishing their course.

ALLs are income contingent, i.e. borrowers repay the loan only if their annual income is above the lower repayment threshold, and their repayment amount is based on their income. Annual incomes are the basis

¹¹ Learner data collected by publicly funded further education providers.

for calculating loan repayments and interest, and getting good income estimates over the working life of borrowers is critical to estimating the RAB charge.

Income modelling starts for a borrower in the first financial year after completing their course. In most cases this will be the first year they are due to make repayments, except during the first years of the policy where it was legislated that the first repayments would not be due until 2016-17.

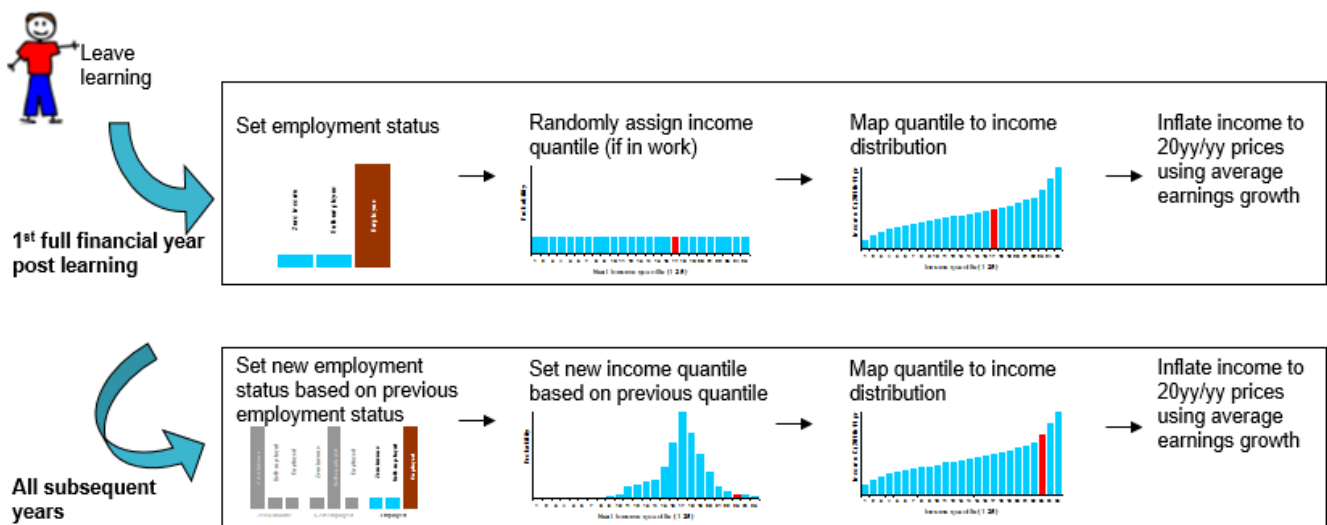

In every simulation each modelled borrower will go through processes to:

1. Set labour market status – transition between ‘employed’, ‘self-employed’ and ‘no income’;
2. Assign position on income distribution – one of the 25 quantiles¹² and
3. Assign annual income based on their position in the income distributions.

The process is summarised below:

Figure 6.1: Income modelling for ALL borrowers

Income over 30 years in more detail ...

4.1 Labour market status

Labour market status in a given year is modelled using a discrete probability matrix which supports three possible outcomes: ‘no income’, ‘employed’ and ‘self-employed’. The matrix has different probabilities depending on the characteristics of the borrower:

- Course level: Level 4+ , Level 3
- Gender: male or female
- Age: single year of age
- Years since completed learning: one year, or more than one year
- Current labour market status: no income, employed or self-employed
- Current year income: one of 25 quantiles, or zero if not in work

¹² The income distribution is split into 25 equal quantile, so each quantile represents 4% of the income distribution. Quantile 1 = the lowest earning. The number of quantiles was determined by considering the greatest detail that the LFS could provide whilst still providing robust estimates.

The data source for the analysis is 40 quarters of Labour Force Survey (LFS). The model uses two sets of labour market assumptions:

- Initial labour market status for those in the first full financial year after their SRDD.
- Probabilities of changing labour market status in all subsequent years.

In the first year after SRDD the model has no knowledge about the working history of each borrower so borrowers are assigned a labour market status only in accordance with the overall employment rates for that age, gender and course level¹³. In all subsequent years each borrower has a probability of changing labour market status, this time taking into account their current labour market status and income quantile (if in work).

Income data for the self-employed is not available from the LFS. This means that income based labour market changes from the employee population are used as a proxy, i.e. if an employed borrower at the bottom of the income distribution has a greater chance of becoming unemployed compared to someone at the top, then a self-employed borrower at the bottom of the income distribution also has a greater chance of becoming unemployed compared to someone at the top.

4.2 Position on income distribution

After labour market status is established in the previous stage, the model assigns the borrower to a quantile on the income distribution. As with labour market status, the model assigns future income quantiles, using different probabilities depending on the characteristics of the borrower:

- Course Level: Level 4+, Level 3
- Gender: male or female
- Age: single year of age
- If in work: current income: one of 25 quantiles
- If out of work: previous income when last in work: one of 25 quantiles or zero if never previously modelled in work.

The LFS does not contain income for the self-employed so it is assumed that transitions across the income distribution for the self-employed occur with the same likelihood as for the employed.

The LFS data only has sufficient information to compare year on year income, it does not hold robust income information from previous employment spells further back in time. As a simplification it is assumed that a borrower returns to work at the same position on the income distribution as they were in their most recent modelled income spell, e.g. if they left work in quantile 10 then when they return to work they will return in quantile 10.

The LFS data suggests that typically those entering work are on lower incomes than the equivalent group leaving work. This would suggest a natural decay in position on the income distribution between jobs, i.e. that learners should return at a lower position on the income distribution. In practice this does not produce a good modelling solution as it creates a heavy penalty for being out of work in a single year and produces unexpected lifetime income paths inconsistent with the original simplified assumption.

4.3 Annual income in nominal terms

The final step in modelling income is to convert an income quantile into actual income for a given financial year. This is achieved by matching the simulated income quantile to historic income quantile distributions. There are different distributions by:

- Course Level: Level 4+, Level 3

¹³ Ideally, the data would be further restricted to learners that are one year post learning but there is insufficient data in the LFS to support this. The initial employment status is quickly eroded by the subsequent employment transition probabilities so has a fairly limited impact on the forecast.

- Gender: male or female
- Age: single year of age
- Years since left learning bands: 1-3 years; 4-10 years; 11+ years

Income distributions are constructed using 8 years of Annual Population Survey (APS). Income is inflated for future growth using OBR projections of average earnings growth for the entire working population. It is also assumed that average earnings growth is even across all quantiles.

5. Life events

From the time a borrower takes out a loan there are additional events that need to be factored in to the modelling, such as mortality, migration, and repayments made directly to SLC. All are modelled at the individual level, but to varying levels of detail.

5.1 Mortality

The Office for National Statistics (ONS) England & Wales population projections include assumptions on mortality rates by gender and single year of age up to 2084. These are used directly to estimate the chance of death for a borrower in any year post taking out a loan, with the key assumption that ALLs borrowers have the same mortality rates as the rest of the population.

It is likely there is some difference in mortality rates for this group compared to the whole of England & Wales, particularly as there is a known link between increased wealth and improved mortality. However, any difference will be minimal and the mortality rates for the working age population are generally very low, further reducing any possible impact.

5.2 Migration

The migration assumptions are split into two components

- Probability of migrating out of the country (out-migrant rate)
- Length of spell out of the country: 3 years, 7 years or 20 years

Out-migrant rates by gender and age are derived by combining Office for National Statistics (ONS) out-migrant estimates with population projections. These are used directly to provide each borrower with a probability of becoming an out-migrant each year.

Once an out-migrant is identified the model assigns a length of stay for the duration abroad. The length and probability of duration are estimated from International Passenger Survey (IPS) data between 1978 and 2012, over which time actual length of stay figures have been relatively stable.

5.3 Permanently unfit for work

The model uses expected flows in to the Support Group of Employment Support Allowance (ESA) as a proxy for the number of people expected to become unfit for work each year. Once identified as unfit for work, a simulated borrower has their remaining loan amount written off.

The ESA Support Group is not a perfect measure of the unfit for work rate, as it is a State Benefit that needs to be actively claimed so is not received by everyone that is eligible. However it provides the closest match in definition to unfit for work which is sufficient for the relatively low number of people that will be affected.

5.4 Extending working lives

State Pension Age (SPA) is due to rise to 67 for men and women by 2024. For women this represents an additional 7 years of work before they will receive their State retirement benefits compared to the observed population in the model data sources.

The model includes a timetable to assign each borrower a State Pension age, from which there is an assumption around what employment rates and income to use given to reflect that people are likely to work for longer. For example, a man with SPA of 65 has the employment rate of a 66 year old when aged 66, but a man with SPA of 66 has the employment rate of a 65 year old when aged 66. This assumes that for men,

the employment rate and income of a 65 year old is held constant between the ages of 65 and the new State Pension age; for women the employment rate and income of a 60 year old is held constant between the ages of 60 and the new State Pension age.

The effects of retirement can be seen in LFS data from as early as age 50. However given the high uncertainty about how people will respond to the rises in State Pension age, and future employment in general, the model uses the simplified assumption.

Data quality

There is a high level of uncertainty around the ALLs RAB and stock charges estimates. At present, we have imperfect information about ALLs borrowers' repayment ability as ALLs are a new product and the first set of repayment data will be available in summer 2018. When we receive the repayment data we will be able to compare this with the assumptions within the model and the resulting impact on the forecast.

Both administrative and survey data are used to inform the assumptions underpinning the ALLs model.

SLC administrative data are used to determine borrowers' characteristics and loan amounts. Historic SLC data should be broadly accurate. SLC quality guidelines are published on the following webpage: <https://www.slc.co.uk/official-statistics/guide-to-our-statistics/compliance.aspx>.

Individualised Learner Record (ILR) data are used to derive and forecast future dropout rates for ALLs borrowers. Even though the ILR data is accurate, there is still a degree of uncertainty around the forecast since we assume future borrowers have similar behaviour to historic borrowers. The ILR quality guidelines are published on the following webpage: <https://www.gov.uk/government/publications/sfr-compliance-with-official-statistics-code-of-practice>.

The Labour Force Survey (LFS) is used to determine employment and income state movements of ALLs borrowers and the Annual Population Survey (APS) for the income distributions. The LFS is a survey of the employment circumstances of the UK population. It is the largest household survey in the UK and provides the official measures of employment and unemployment. The APS is a supplement to the LFS data. The APS is published quarterly and each dataset contains 12 months of data. The sample size for each dataset is approximately 170,000 households and 360,000 individuals.

The employment and income status assumptions are two of the most important assumptions within the model. We derive both of those from the LFS assuming that Further Education achievers in the LFS data are representative of ALLs borrowers.

The LFS data has various limitations and a key drawback is that only one year of earnings history is available. Also, the LFS does not capture self-assessment income, but does include a flag to identify employment status. The key assumptions arising from the data limitations are listed below:

- The model 'forgets' a borrower's past history of employment statuses prior to the current year, since a one-step transition approach is used. This means that a learner who has been unemployed for 10 years has equal chance of employment as someone who has been unemployed for just one year.
- Transitions between employment states for the employed are used as a proxy for self-employed people. Self-employed people are assumed to have the same income distribution as employed learners.
- We assume that a borrower who has left the labour market will return to work at the same position on the income distribution as they were in their most recent employment spell.

Despite these limitations, the LFS is the only data source currently available that has a sufficiently large sample to allow analysis of income by age and type of qualifications and transitions in and out of employment. In the future it will be possible to use actual repayment data to improve these assumptions, as well as consider how data from the new Longitudinal Education Outcomes study could also be incorporated into the modelling.

The model is also dependent on the OBR macroeconomic forecasts that it uses to uprate earnings, calculate interest rates and repayment thresholds, and to discount future repayments to present values. Any significant changes to the economy from these forecasts could affect the repayments that will be made on the Advanced Learner Loans.

7. Uses of these statistics

These forecasts show how much Government outlay on students loans is expected to be in future, how much is expected to be repaid and how the student loan book may grow in the future. The Department for Education uses these models for financial planning and in the development of student funding policies.

These forecasts are also used in the Department for Education's annual accounts in the valuation of the student loan book. The stock and RAB charges are used to impair the face value of the loan books and the value of new loans being issued respectively, to reflect that the value of the future repayments that will be received in relation to these loans is less than the long term cost of Government borrowing that would be necessary to cover its outlay on student loans.

These models are used by the Office for Budget Responsibility as part of its estimates of public sector borrowing, including in its Economic and Fiscal Outlook that presents economic forecasts five years into the future and its Fiscal Sustainability Report that presents long term projections of UK public finances.
