## Acknowledgements

The authors of this report wish to thank all the many people who contributed to this survey. This includes firstly, all the parents, children and young people who completed the questionnaires, interviews and diet diaries so enthusiastically and showed much interest in the survey. Secondly, our thanks go to all the interviewers who worked on the survey for their interest in the survey and the professional way in which they conducted the interviews which contributed to the success of this survey.

We would like to acknowledge the contribution of the following people to the survey:

- Staff at ScotCen who were responsible for the early work on the design and setting up of the survey: Catherine Bromley and Lyn Jones.  
Lisa Given for all her work in getting the survey into the field and Lesley Birse and Ann Rennie for administrative help.
- The Blue Team, headed by Theresa Patterson at NatCen operations centre in Brentwood.
- Sarah Tipping for statistical support and Steve Edwards for programming support, both based at NatCen, London.
- Caireen Roberts and Lesley Wells, both formerly of Kings College, London for their work on the 24-hour recall documentation for the survey and training at interviewer briefings.
- Yasmin Hosny formerly of Kings College, London for her assistance with editing and checking the 24-hour recalls.
- Batul Haque formerly of Kings College, London for her work obtaining product information on new products that arose from the 24-hour recalls.
- Janet Kyle and Gladys McPherson at the University of Aberdeen for their expert assistance with the nutrient analysis for the Food Frequency Questionnaires
- Nicola Cochrane, Fiona Comrie, Kim Giles and Mark Taylor, also at the University of Aberdeen, for assistance with the data entry of the food frequency questionnaires and the diet diaries.
- Claire Fyfe at the Rowett Research Institute for checking the data entry for the diet diaries
- Staff at the Food Standards Agency Scotland, Heather Peace, Anne Milne and Gillian Purdon for their support and guidance throughout the project.

## EXECUTIVE SUMMARY

Diet is an important determinant of health. Dietary targets for the Scottish population were published in *Eating for Health: a Diet Action Plan for Scotland*<sup>1</sup> in 1996. A working group set up to monitor progress in reaching these targets recommended that '*where data is currently lacking, as for non-milk extrinsic sugars in children, interim studies may need to be set up*'.<sup>2</sup>

The 'Survey of sugar intake among children in Scotland' was commissioned by the Food Standards Agency Scotland (FSAS) in 2005 to provide robust information on the diet of Scottish children, with a particular focus on the intake of non-milk extrinsic sugars and sugar-containing foods. The survey was carried out by a consortium of four organisations: the Scottish Centre for Social Research, the University of Aberdeen, the Rowett Research Institute and King's College London. Fieldwork for the survey was conducted between May and September 2006.

Using the Department of Work and Pensions Child Benefit records, a named sample of 2800 Scottish children aged between 3 and 16 years on 1st May 2006 was drawn from 80 postcode sectors across Scotland. One child per household was selected. After exclusions and an initial opt out period, a Food Frequency Questionnaire (FFQ) was sent to the remaining 2498 children in the sample. This was collected by an interviewer when they called to conduct an interview. Information on household composition and sociodemographic data was collected and the child's height and weight were measured.

Two randomly selected sub-samples were drawn from the whole sample. One sub-sample was asked to complete a four day diet diary, the other, drawn from only 40 of the postcode sectors, was asked to complete a single 24-hour recall.

Face to face interviews were conducted with 1700 respondents and 1512 FFQs were returned giving a combined response rate for these two items of 66%. A total of 186 diaries (60%) were completed and returned and 424 24-hour recalls (99%) were completed. Response rates for combined FFQ and interview were highest amongst those in the 8-11 year age group for both sexes (71% for both).

Nutrient intake as recorded by the FFQ and either the diet diary or 24-hour recall were compared for 153 and 350 children respectively. Energy intake from the FFQ was 10.5% higher than that for the diet diary and 5.5% higher than that for the 24-hour recall, with the difference being greater in children aged 3-11 years than those aged 12-17 years.

There was no significant difference in the intake of NMES (% food energy) as recorded by the FFQ (16.0%) or the diet diary (14.9%). The intake of NMES (% food energy) was also very similar by the FFQ (17.4%) and the 24-hour recall (16.6%) though in this case the difference was statistically significant. There was no significant difference in intake of total fat or saturated fatty acids (% food energy) between the FFQ and either the diet diary or the 24-hour recall. Absolute intakes of iron, calcium and all macronutrients apart from protein were all significantly higher as recorded in the FFQ than in the diet diaries or the 24-hour recall.

### ***Intake of food groups***

Over 95% of children reported consuming: pasta, rice and pizza; bread excluding wholemeal; biscuits, cakes and pastries; milk and cream; yoghurt and fromage frais; meat and meat

dishes; processed meat; vegetables; chips; crisps and savoury snacks; fruit; confectionery and soups and sauces at least once a month: 59% of children reported consuming wholemeal bread and 39% oily fish and dishes at least once a month.

Younger children were more likely to consume wholemeal bread, unsweetened breakfast cereals, yoghurt and fromage frais, ice-cream, fats and oils and white fish, shell fish and fish dishes. Older children were more likely to consume chips, fried and roast potatoes and potato products, nuts and seeds, non-diet soft drinks and beverages.

Those living in less deprived areas (as defined by quintile of the Scottish Index of Multiple Deprivation or SIMD) were more likely to consume wholemeal bread, cheese, oily fish and dishes and fruit juice and less likely to consume diet soft drinks than those living in more deprived areas.

### ***Intake of energy and sugars***

Energy intake was significantly higher in boys than girls overall and increased with age in boys but not in girls. The median intake of NMES as percentage food energy was 17.4% and sucrose 13.4%. NMES and sucrose as percentage food energy intake both increased with age group.

Higher energy intake was associated with increasing deprivation. NMES and sucrose contributed a higher proportion of food energy and, intrinsic and milk sugars contributed a lower proportion of food energy in the more deprived quintiles.

### ***Contribution of food groups to intake of energy and sugars***

The food groups contributing the highest proportion of total energy intake were biscuits, cakes and pastries (9%) and bread excluding wholemeal (8%). Non-diet soft drinks were the major contributors to NMES (17%), along with confectionery (12%) and biscuits, cakes and pastries (12%).

There were highly significant overall and linear associations between the SIMD quintiles and the percentage contribution of several food groups to both energy and sugars. Children in the more deprived areas derived a lower proportion of energy from pasta, rice and other cereals and a higher proportion from crisps and savoury snacks than children in the less deprived quintiles. These children also obtained a lower proportion of total sugars from fruit, and a higher proportion from confectionery and non-diet soft drinks.

There was a more marked pattern for the contribution of food groups to NMES intake, particularly for drinks. Children in the more deprived areas obtained a higher percentage of NMES from non-diet soft drinks (23% in the most deprived quintile vs. 14% in the least deprived quintile) and a lower percentage from fruit juice (3% in the most deprived quintile vs. 9% in the least deprived quintile).

NMES intake as a percentage of food energy was considerably higher than the UK recommended population average for adults ( $\leq 10\%$  of total energy or  $\leq 11\%$  of food energy) and the Scottish Dietary Target for children ( $\leq 10\%$  of total energy), with the values reaching 19.8% in boys and 18.7% in girls aged 15-17 years.

### ***Intake of fat and saturated fatty acids***

The total intake of total fat and saturated fatty acids as percentage food energy were 32.9% and 13.8% respectively. There was no significant association between total fat or saturated fatty acids as percentage food energy and SIMD.

There were significant differences and a linear association between deprivation and the contribution of processed meats, crisps and savoury snacks to the intake of total fat and saturated fatty acids.

The mean intake of total fat as percentage of food energy was lower than the DRV population average and that recommended in the Scottish Dietary Targets (35% and  $\leq 35\%$  respectively) in all age and sex groups. The mean intake of saturated fatty acids was above the recommended levels of 11% food energy in all age and sex groups.

### ***Overweight and Obesity***

Overall the prevalence of overweight and obesity was 14% and 17% respectively. There were no significant differences between the sexes in the prevalence of overweight and obesity overall, 13% of boys and 15% of girls were overweight and 16% of boys and 18% of girls were obese.

There was no evidence of a linear association between BMI and deprivation although children in the least deprived (1st) quintile had the lowest mean BMI (17.9 kg/m<sup>2</sup>) while those in the 2nd quintile had the highest (18.6 kg/m<sup>2</sup>).

There was an overall association but no linear association between prevalence of the combined category of *overweight including obese* and SIMD. The highest proportion of children in the *overweight including obese* category appeared in the middle (3rd) quintile, (33% boys and 38% for girls). The lowest proportion of children in this category was in the least deprived (1st) quintile (25% for both sexes).

### ***Physical Activity***

Children's physical activity levels were categorised as:

- High: active for 60 minutes on 7 days in the last week.
- Medium: active for 30-59 minutes on 7 days in the last week.
- Low: active at a lower level or not active at all.

Any activity during school lessons was not included in these estimates.

Overall, 86% of children reached the 'high' activity level – the current recommended level for children, though it should be noted that fieldwork for this survey was conducted over the summer months including over the school summer holidays when activity levels may have been higher than at other times of year.

More boys reached the high level of physical activity than girls (89% vs. 83%). A further 5% of boys and 9% of girls reached the medium activity level. There was a decline in activity levels in the 12-17 year age group in both sexes but the decline was greater for girls than boys.

There was no clear pattern in the relationship between those meeting the physical activity recommendations and deprivation.

### *Time spent at a screen*

Boys spent an average of 2.2 hours a day and girls 2.0 hours a day sitting in front of a screen (TV, computer or video game). The time spent in front of a screen increased linearly with age group for both sexes, 14 % of both boys and girls, aged 12-17 years, spending on average 4 hours a day in front of a screen compared to 5% of boys and 4% of girls in the youngest age group (aged 3-7 years).

### *Physical Activity and BMI*

To examine the levels of physical activity by BMI, children were classified into one of two BMI groups; *neither overweight nor obese* or *overweight including obese*.

A higher proportion of children in the *neither overweight nor obese* category reached the recommended level compared with those in the *overweight including obese* category (88% vs. 81%). The differences were not significant for the oldest age group (12-17 year olds).

For all children and for boys alone there was a significant association between BMI category and time spent sitting in front of a screen. A higher proportion of children in the *overweight including obese* category spent more than 3 hours in front of a screen than those in the *neither overweight nor obese* category (25% vs. 20%). For boys the proportions were 28% vs. 21%.

### **Dental Health**

Over half (56%) of all children had received treatment for decay (either fillings or teeth taken out), and the likelihood of receiving treatment for decay increased with age. The proportion of children receiving treatment for decay rose from 26% amongst 3-7 year olds to 74% amongst 12-17 year olds.

Treatment for decay was associated with increasing deprivation in both sexes. Boys in the most deprived quintile were twice as likely to have had treatment for decay as boys in the least deprived quintile (71% vs. 35% respectively). For girls the difference between the highest and lowest quintiles was not as great (65% vs. 43%).

### *Association between diet and dental disease*

NMES intake was significantly higher in children who had received treatment for decay (mean 18.5% food energy) than in children who had not (mean 16.1% food energy). This difference was significant in boys and in girls, and was more evident in older children than in younger children. Children who had received treatment for decay had significantly higher intakes of biscuits, cakes and pastries, confectionery, crisps and savoury snacks, and non-diet soft drinks than children who had never received treatment for decay.

### **Conclusions and Recommendations**

The intake of NMES in Scottish schoolchildren is considerably higher than recommended levels, particularly in older children and those living in more deprived areas, due to high consumption of non-diet soft drinks, confectionery and biscuits, cakes and pastries. The high intake is likely to be contributing to dental disease. While there was no evidence from this survey that diet was associated with overweight or obesity, reducing intake of energy intake by reducing NMES intake would make a positive contribution to prevention of overweight and

obesity. Initiatives such as 'Hungry for Success'<sup>3</sup> and the Schools (Food and Nutrition) Act<sup>4</sup> which focus on improving the provision of food in schools should have beneficial effects on NMES intake within schools but wider initiatives may be needed to reduce the intake of foods high in NMES outside school to alter this pattern in future generations.

### **Recommendations**

Use of the Child Benefit records as the sampling frame should be considered in any future study monitoring children's diets.

The FFQ as used in this study proved to be a cost effective and robust method for measuring intake of NMES and fat and saturated fatty acid as percentage food energy. It is recommended that this method be considered in monitoring the intake of these nutrients.

Measures need to be taken to reduce the high intake of the main sources of NMES identified in this survey, namely non-diet soft drinks, biscuits, cakes and pastries and confectionery. Such measures should be directed at all children.

Consideration should be given to repeating this survey at regular intervals to provide data on ongoing progress made towards Scottish Dietary targets for NMES and fat intake. Such a survey would also serve to evaluate the impact of policy initiatives directed at improving children's diet.

Research is needed to develop interventions to reduce intake of NMES and saturated fatty acids in children's diets to reach the Scottish Dietary Targets. In addition, measures need to be taken to ensure that a reduction in NMES and saturated fatty acids is complemented by an increase in foods rich in complex carbohydrate to provide a healthy, balanced diet.

## NOTES TO TABLES

The following conventions have been used in tables:

1. [ ] are used to warn of small sample sizes i.e. if the unweighted base is less than 50. Statistical tests of significance were not carried out if figure in cell was based on unweighted base of less than 50.
2. A p-value for the overall association of  $<0.05$  indicates that at least one group differs significantly from at least one other.
3. Row or column percentages may not add exactly to 100% due to rounding.
4. Both weighted and unweighted base numbers are presented. Weighted base numbers reflect the relative size of each group in the population whereas unweighted bases represent the actual number of respondents in any specified group.
5. When the p-value for linear association is statistically significant ( $p<0.05$ ), the direction of the association is indicated in the footnote to the table.
6. Due to the transformations which were carried out for skewed data, the sum of NMES and intrinsic and milk sugars does not equal the value for total sugars. For the same reason, percentage contribution from all food groups to nutrient intake does not equal 100%

# 1 INTRODUCTION

## 1.1 Background

The importance of diet for the health of the Scottish population was highlighted in 1993 in a report published by the Scottish Office<sup>1</sup>. Following this report, dietary targets for the Scottish population were published as part of the Scottish Diet Action Plan<sup>2</sup>. These targets were based on the UK Dietary Reference Values<sup>3</sup> for selected nutrients and on patterns of food consumption in Scotland derived from the National Food Survey<sup>4</sup>. The targets are shown in Table 1.1.

**Table 1.1 Scottish Dietary Targets**

<b>Food or nutrient</b>	<b>Target</b>
Fruit and vegetables	Average intake to double to more than 400g per day.
Bread	Intake to increase by 45% from present daily intake of 106g, mainly using wholemeal and brown breads.
Breakfast cereal	Average intake to double from the present intake of 17g per day.
Fats	Average intake of total fat to reduce from 40.7% to no more than 35% of food energy. Average intake of saturated fatty acids to reduce from 16.6% to no more than 11% of food energy.
Sodium	Average intake to reduce from 163 mmol per day to 100 mmol per day (the equivalent of 6g salt).
Sugar	Average intake of non-milk extrinsic sugars in adults not to increase. Average intake of non-milk extrinsic sugars in children to reduce by half to less than 10% of total energy.
Total complex carbohydrates	Increase average non-sugar carbohydrates intake by 25% from 124g per day through increased consumption of fruit and vegetables, bread, breakfast cereals, rice and pasta and through an increase of 25% in potato consumption.
Fish	White fish consumption to be maintained at current levels. Oil-rich fish consumption to double from 44g per week to 88g per week.
Breastfeeding	The proportion of mothers breast-feeding their babies for the first 6 weeks of life to increase to more than 50% from the present level of around 30%.

The Scottish Dietary Targets were originally intended to be achieved in 2005 though the timescale has since been extended to 2010. In 2003 a working group was established to monitor progress towards the Scottish Dietary Targets. The suitability of existing data sets for monitoring progress were reviewed. The best source of information on progress over the period was found to be the National Food Survey, which was replaced by the Expenditure and Food Survey in 2001. These surveys have been carried out annually since 1940 and

collect information on food consumption and expenditure which is converted to nutrient intake. However, the data in these surveys is collected at a household level so cannot provide information on the intake of sub-groups such as children. A key recommendation of the report of the working group on monitoring was that '*where data is currently lacking, as for non-milk extrinsic sugars in children, interim studies may need to be set up*'<sup>5</sup>.

The diet of schoolchildren in Scotland has been the focus of several policy initiatives, notably 'Hungry for Success',<sup>6</sup> launched in 2003, which aims to improve the nutritional content and uptake of school meals. The survey described in this report was commissioned by the Food Standards Agency Scotland (FSAS) in 2005 to provide robust information on the diet of Scottish children, with a particular focus on the intake of non-milk extrinsic sugars and sugar-containing foods. As the risk of dental caries has been positively related to the amount and frequency of consumption of non-milk extrinsic sugars, and dietary sugars may also contribute to the general excess food energy consumption responsible for the development of obesity,<sup>7</sup> the survey included questions on dental health and physical activity. Height and weight measurements were also taken.

## 1.2 Classification of sugars

Sugars are soluble carbohydrates which are oxidised in the body to provide energy, water and carbon dioxide. Free sugars in food include monosaccharides, and disaccharides which are polymers of two monosaccharides. The most common monosaccharides in foods are glucose, which is found in small amounts in some fruits and vegetables, and fructose which is found in fruits, honey and invert sugar syrups which are widely used in processed foods. The most common disaccharide in foods is sucrose, a polymer of glucose and fructose, which is found in sugar cane and sugar beet and used to produce table sugar. Other disaccharides in foods are lactose, a polymer of glucose and galactose which is found in milk and milk products, and maltose, a polymer of two glucose molecules, which is found in sprouted grains.

The Department of Health report on Dietary Sugars and Human Disease<sup>7</sup> proposed a classification of sugars based on their physical location within a food (which influences the availability for bacterial metabolism in the mouth and the speed of absorption) and the type of food in which they are found. For example, the sugar in milk is almost all lactose, which is thought to make a negligible contribution to dental caries. The proposed classification, which is used in this report, is:

- Intrinsic sugars: sugars forming an integral part of certain unprocessed foodstuffs, i.e. enclosed in the cell, the most important being whole fruits and vegetables
- Extrinsic sugars, which are not located within the cellular structure of a food can be further divided into
  - Milk sugars, occurring naturally in milk and milk products
  - Non-milk extrinsic sugars, which includes fruit juices, honey, and 'added sugars' which comprise both recipe sugars and table sugars.

It should be noted that non-milk extrinsic sugars (NMES) are not chemically distinct from intrinsic sugars and that there is therefore no laboratory test capable of measuring the NMES content of foods directly. The data in this report are based on nutritional information from the National Diet and Nutrition Survey (NDNS) nutrient databank (see Appendix A, Section 1.6.3) which uses the following criteria to estimate the NMES content of foods.<sup>8</sup>

- All sugars in fruit juices as well as table sugar, honey and the sucrose, glucose and glucose syrups added to foods are classified as extrinsic

- All sugars in fresh fruit and vegetables are classified as intrinsic
- Sugars naturally present in foods that are canned, stewed, dried or used in preserves are classified to be half extrinsic and half intrinsic. Added sugars or syrup in preserves are classified as extrinsic
- Lactose, whether in a milk product or not, is considered as milk sugar. The group of 'intrinsic and milk sugars' is the sum of intrinsic sugars and lactose
- The proportions of intrinsic and extrinsic sugars in other mixed and prepared foods are calculated according to the above principles.

### **1.3 Aims of the survey**

The principal aim of the survey was to estimate intake of NMES and other macronutrients and foods in a nationally representative sample of Scottish children aged 3-16 years.

Additional objectives were:

- To compare the intake of NMES and other macronutrients and micronutrients between sub-groups divided by age, sex, deprivation category and rural-urban residence
- To estimate the prevalence of overweight and obesity in all children and in sub-groups divided by age, sex, deprivation category and rural-urban residence
- To investigate associations between energy, NMES and fat intake and overweight and obesity in all children and in sub-groups divided by age and sex
- To determine the levels of physical activity in all children and in sub-groups divided by age, sex, deprivation category and rural-urban residence
- To assess associations between physical activity and inactivity and overweight and obesity in all children and in sub-groups divided by age and sex
- To assess dental health in all children and in sub-groups divided by age, sex, deprivation category and rural-urban residence
- To assess associations between NMES intake and dental health in all children and in sub-groups divided by age and sex.

The survey was carried out by a consortium of four organisations: The Scottish Centre for Social Research (part of the National Centre for Social Research); the Department of Environmental and Occupational Medicine and the Department of Public Health, University of Aberdeen; the Rowett Research Institute, Aberdeen and the Nutritional Sciences Division, King's College London.

The fieldwork for the survey was conducted between May and September 2006.

### **1.4 Plan of report**

Chapter 2 gives an overview of how the survey was conducted and the rationale for the dietary assessment methods used in the survey. A description of each dietary method and how the data collected was analysed is also presented.

The achieved response to each component of the survey by age and sex and Scottish Index of Multiple Deprivation (SIMD) is provided in Chapter 3. The results of the use of two different levels of incentive for completion of one of the dietary assessment methods, the Food Frequency Questionnaire (FFQ), are also given in Chapter 3.

Chapter 4 compares the nutrient and energy intakes assessed using the different dietary assessment methods. Nutrient and energy intakes for those participants who completed both the FFQ and diet diary were compared and similar comparisons were made for those who

completed the FFQ and 24 hour recall. There is also a discussion of the response to the different methods.

Chapters 5, 6 and 7 report on nutrient intakes as reported in the FFQ. Chapter 5 focuses on intake of food groups and supplements, Chapter 6 on intake of energy and sugars and Chapter 7 on intake of other nutrients.

Chapter 8 presents the anthropometric measures and provides estimates of the prevalence of overweight and obesity in children. The association between high energy food groups, energy intake, and total fat, saturated fat, total sugars and NMES as % energy and overweight and obesity is explored.

Children's participation in physical activity and an estimate of the proportion who meet the Scottish Executive's recommended levels of physical activity are presented in Chapter 9. The association between physical activity and overweight and obesity is explored.

Chapter 10 reports on dental treatment received, particularly treatment for dental decay. The association between treatment for dental decay and selected food groups and nutrients is investigated.

The report concludes in Chapter 11 with a discussion of findings of the survey and implications for practice.

Appendices to the report are available separately as pdf files.

## **2 METHODOLOGY**

This chapter gives an overview of the sample design and survey methodology and describes each of the dietary assessment methods used. Details of how the dietary data was analysed is also provided. Further details of the methodology can be found in Appendix A.

### **2.1 The sample**

The sample for this study was drawn from The Department of Work and Pensions (DWP) Child Benefit records. A multi-stage stratified probability sample design was used to provide a sample of 2498 named children which was expected to yield an achieved sample of approximately 1600 respondents. The sample was selected from 80 sampling points across Scotland, including the larger island groupings with sampling points selected with probability proportionate to the number of eligible children within them.

All children aged between 3 and 16 years on 1<sup>st</sup> May 2006 were included in the sample frame. Only one child per household was randomly selected to take part in the study.

Two randomly selected sub-samples were drawn from the whole sample. One of these sub-samples was asked to complete a four day diet diary. The second sub-sample which was selected exclusively from 40 of the 80 sampling points was asked to complete one 24-hour recall interview. The two sub-samples were mutually exclusive - a child selected for one group was excluded from the other.

### **2.2 Overview of survey methodology**

The adult claiming child benefit on behalf of the named child in the sample was contacted by letter on behalf of the HM Customs and Revenue holders of the DWP Child Benefit records. The letter informed them that they had been selected to take part in the survey and gave details of what the survey was about and how to opt out if they did not want to participate (copies of letters can be found in Appendix B).

All those remaining in the sample after opt out were sent a second letter on behalf of the research team and the FSAS. This asked recipients to complete the accompanying Food Frequency Questionnaire (FFQ) and also invited them to take part in a face to face interview. The interviewer collected the completed FFQ when they called to conduct the interview. An initial check of the completed FFQ was made to ensure that there were no obvious gaps or errors. If the FFQ had not been completed when the interviewer called the respondent was asked to post it back. A second copy of the FFQ was left with participants who reported that they had not received or had mislaid the original copy.

The face to face interview collected information on the household composition and sociodemographic data relating to the household and main food provider. The main food provider was defined as the person in the household with the main responsibility for shopping and preparing food for the child. Data were also collected on the named child's physical activity levels over the previous week and dental health. The child's height and weight were also measured and used to calculate body mass index (BMI). (See Appendix C)

There were two versions of the FFQ: one for children aged 3-11 years and the other for children aged 12 -16 years. A parent or guardian was asked to complete the FFQ and the interview on behalf of the children under 12 years with help from the child where appropriate.

Those aged 12 years and over in the sample were asked to complete the FFQ and the questions in the interview relating to dental health and physical activity with help from a parent or guardian as necessary. A parent or guardian was asked to respond to the sociodemographic questions in the interview.

A high street shopping voucher was included with the letter of invitation and FFQ as an incentive to take part in the survey. Two levels of incentive were used to determine whether a higher level of incentive had an effect on response rate. Approximately half of the sample were sent a £1 high street shopping voucher and the other half a £5 voucher. Interviewers were not aware who had received which level of incentive.

Following the face to face interview, one sub-sample was asked to complete a prospective four day diet diary in which they were asked to record all they had eaten and drunk over a four day period. The four day period included at least one weekend day. Participants were offered a £10 high street shopping voucher if they agreed to complete and return the diet diary. The voucher was given to the respondent in the course of the interview when they agreed to complete the diary.

Two reminders were sent out to those who had not returned the FFQ at 2 weeks and 4 weeks after the interview was conducted. Those who had not returned the diaries were contacted by telephone to remind them to return the diet diary. A postal reminder was sent if the initial telephone reminder did not result in the return of the diet diary.

The second sub-sample was asked to complete a single 24-hour multiple pass recall in which details of everything the respondent had eaten and drunk over the previous 24 hours were collected. To ensure that different eating patterns over the weekdays and weekend days were captured, interviewers were asked to conduct interviews which included a 24-hour recall on a range of different days of the week. Section 3.1.2 gives details of the distribution of the days reported. Twenty four hour recalls were carried out during the same interview as the face to face questionnaire. No additional financial incentive was offered to this sub-sample.

## **2.3 Dietary assessment methods**

### **2.3.1 Overview of methods**

The methodology for assessing intake in dietary surveys needs to be carefully chosen to be fit for purpose according to the population group and the nutrients of interest. Epidemiological surveys often use FFQs which consist of a list of foods and drinks containing the food(s) and/or the nutrient(s) of interest for which the respondent reports their frequency of consumption. FFQs have many advantages for large-scale surveys of habitual diet, notably that respondents are asked to estimate their food consumption over several months rather than several days and that responses can be pre-coded which also facilitates data entry and analysis. However, the method relies on the respondents' ability to classify foods into the categories listed in the questionnaire and on their ability to estimate their habitual intake of each food. In addition, average values for nutrient content of food and portion size are applied to all respondents, so that the nutrient intake results are more likely to be valid for groups than for individuals. To evaluate the possible impact of these limitations of FFQs, comparison with other methods of assessing the intake of the nutrients of interest in the study population is necessary, with diet diaries considered to be the method of choice for comparison.<sup>1</sup>

For the present study, FFQs were considered to be the most appropriate method due to the ability to estimate intake over several months and the cost-efficiency for a large-scale survey. To assess the relative validity of the FFQ, a 4 day diet diary was used in a sub-sample of the study population.

A single 24-hour multiple pass recall was collected for a further sub-sample of the study population. The primary aim of this data was to provide comparability of the results of the present study with those obtained in other UK-wide dietary surveys which use the 24-hour multiple pass recall method, such as the Low Income Diet and Nutrition Survey (LIDNS)<sup>2</sup>. It should be noted that in the LIDNS 24-hour recall, data was collected for four days, unlike the present study which collected data for a single day. This was because in the present study the aim was to provide an estimate of the population mean rather than to assess individual values. The comparison of the median nutrient intake by the 24-hour multiple pass recall method with the data obtained from the FFQ in this sub-group was also used to provide further insight into the relative validity of the nutrient intake estimates derived from the FFQ.

Interviewers were trained in checking the FFQs for completeness and in instructing children and parents or guardians on how to complete the diet diaries. Those interviewers who carried out the 24-hour recall were given appropriate training on how to conduct the recalls (see Appendix A for further details on the methodology of the dietary assessment methods).

### **2.3.2 Food frequency questionnaires (FFQs)**

The FFQs used in this survey were based on the Scottish Collaborative Group FFQ (SCG FFQ), which has been widely used in epidemiological studies in Scotland.<sup>3</sup> The versions used in this survey were modified from a FFQ developed for use in pre-school children (version C1) for which validity in comparison with 4-day non-weighed diet diaries has been reported<sup>4</sup>. Two new versions were developed:

- version C2 for children aged 3-11 years which included instructions for completion by a parent or guardian with help from the child
- version C3 for young people aged 12-16 years with instructions for completion by a young person with help from their parent or guardian

Examples of the two FFQs can be found in Appendix D (i) and Appendix D (ii).

Version C2 lists 140 foods or drinks each with a measure representing a small portion for each item. Examples of food measures were shown in a photograph on the front cover of the FFQ. Participants were asked to estimate the frequency and amount of each food or drink consumed in a typical week by selecting one of nine options, ranging from '*rarely or never*' to '*7 or more measures per day*'. Additional information was obtained on the brand of spreads and cooking oils used, use of dietary supplements and of any foods consumed not listed in the FFQ.

Version C3 was very similar to version C2 apart from the addition of another six items in the beverages section to include coffee and a range of alcoholic drinks. The measures given on the FFQ for each food were the same as those in C2 as participants were able to increase the number of measures consumed to describe larger portions. However, for a few foods for which the measure was poorly defined (e.g. one serving) the weight used in calculation of the nutrient intake was higher in version C3.

A pilot study of both versions of the FFQ was carried out with 84 children aged 5-16 years in Aberdeen. The majority of parents and children in the pilot reported that they found the

questionnaires 'fairly easy' or 'very easy' to complete. A few additional foods (e.g. smoothies) which were reported by the participants in the pilot study were added to the FFQ food lists. A report on the FFQ pilot study is provided in Appendix E.

The completed questionnaires were checked by the interviewers for missing or ambiguous data (e.g. on supplements or cooking oil brand). Data from the completed questionnaires were entered into an ACCESS database file. The quality of data entry of a random 10% sub-sample of the questionnaires was checked by a second researcher and the error rate in data entry was found to be 0.4%. Nutrient intakes were calculated from the FFQs using an in-house calculation programme, developed by the University of Aberdeen. This incorporates information on the weight of each food measure, the frequency of consumption of each food and the nutrient composition of each food. For this survey nutrient composition was derived from the National Diet and Nutrition Survey<sup>5</sup> (NDNS) nutrient databank (see Section 2.3.5).

### **2.3.3 Diet diaries**

The diet diaries used in this survey were based on children's diet diaries previously developed by the University of Aberdeen. The diet diaries were non-weighed, i.e. participants were asked to estimate the weight or volume of each food or drink using household measures, weights provided on the packaging, or colour food photographs reproduced in the back of the diaries. These photographs were reproduced from a *Photographic Atlas of Food Portion Sizes*.<sup>6</sup> Participants were asked to include one weekend day in the four days for which they kept the diary.

Two versions of the diet diaries were used; one for children aged 3-11 years and the other for those aged 12-16 years (see Appendix F for examples of the diaries). The format of the diet diaries was the same for the two groups but the photographs in the diet diaries for those aged 12-16 years had larger portion sizes for some foods than those used in the diaries for children aged 3-11 years. Again the diet diary for younger children was designed for completion by the parent or guardian while the diet diary for older children was designed for self-completion.

The diet diaries contained written instructions which were reinforced by the interviewers when the method was introduced. Participants who later had questions about the completion of the diet diary were able to contact researchers in Aberdeen on a Freephone telephone number.

The diet diaries had also been tested in the same pilot study as the FFQs (see Section 2.3.2). The majority of parents or children in the pilot found the diet diary 'fairly easy' or 'very easy' to complete (see Appendix E).

Interviewers sought written consent from those agreeing to complete the diary to allow their contact details to be sent to researchers in Aberdeen. This enabled researchers to enquire about any missing information in the diet diaries if necessary and to telephone any participants who had agreed to complete a diet diary but for whom no diary had been received.

The foods and drinks listed in the diet diaries were coded by a single researcher in Aberdeen using the NDNS nutrient databank and data entered using the Rec24 programme (see Section 2.3.5). To ensure consistency of coding, a single researcher estimated the weights of all foods and drinks using the information provided by the participants and published weights of food portions<sup>6,7</sup>. For staple foods where the description of the food type was incomplete (e.g. the type of milk or bread) details were sought from the respondent's FFQ. If the FFQ did

not provide the required information a default food type was used based on those used in LIDNS<sup>2</sup>. For other queries the participant was contacted by telephone, for example, one common error was to report consumption of breakfast cereals with no milk. Diaries which contained information for fewer than 4 days were rejected. A second researcher checked all the entered data before calculation of the nutrient intake using the NDNS nutrient databank<sup>5</sup> (see Section 2.3.5).

### **2.3.4 24-hour multiple pass recall**

The 24-hour recall method used was the 'multiple pass' method, based on that used by the US Department of Agriculture,<sup>8</sup> modified for use in the Low Income Diet Methods Study<sup>9</sup> (LIDMS) and the Low Income Diet and Nutrition Survey<sup>2</sup> (LIDNS). Information was collected in three phases in a single interview, allowing the respondent three opportunities to recall what they ate and drank over the previous 24 hour period (see Appendix G for examples of the 24-hour recall fieldwork documents).

In the first instance participants were asked to provide a 'quick list' (first pass) of all the items that they had eaten or drunk on the previous day, from midnight to midnight. Second, the interviewer went through the 'quick list' gathering further details to identify fully each item and to quantify the amount consumed. The 'third pass' involved the interviewer going through the list of food and drink recalled and probing for additional items consumed at each occasion, as well as between occasions. Finally participants were asked a series of questions on drinking water, dietary supplements and whether or not the day's intake had been typical. Further details are given in Appendix A.

A telephone query line was set up at King's College London (KCL) for the interviewers to contact researchers to ask questions about any aspect of carrying out the 24-hour recall during the fieldwork period.

Food coding and data entry of the 24-hour recalls were generally carried out in line with LIDNS.<sup>2</sup> Trained coders entered the data and researchers based at KCL checked any queries flagged up by the coders. All foods and drinks were coded using the NDNS nutrient databank and data were entered using the Rec24 program (see Section 2.3.5).

The Rec24 program incorporates checks such as identifying missing codes and food items where the weight of food calculated exceeded a maximum value or where inappropriate portion codes had been used (for the 24-hour recall only).

A random 10% of all of the 24-hour recalls were checked for food and portion code entries. The aim of this task was to identify any problems with coding. At the end of the data entry for the 24-hour recall, age and sex specific histograms showing the distribution of intake for energy and 23 nutrients were produced and cut-offs specific to each age and sex group identified high/extreme values in the distribution. This resulted in data for approximately 110 respondents being checked against the original paper 24h recall record sheet which identified a small number of incorrect food or portion codes (about 3% of outliers).

Since only 1 day of data was collected for the 24-hour recall, respondents were excluded from the survey if a large part of the day's intake was recorded as missing.

### **2.3.5 NDNS databank, data entry and food coding**

Data from the diet diaries and the 24-hour recall were entered into the Rec24 program developed by NatCen using Blaise software. The program was modified for the diet diaries to accept data for four consecutive days.

The NDNS databank was used for the nutrient analysis of all three dietary assessment methods. The nutrient databank was originally developed for the then Ministry of Agriculture, Fisheries and Food (MAFF)<sup>10</sup> for the Dietary and Nutritional Survey of British Adults.<sup>11</sup> It was updated for the National Diet and Nutrition Surveys (NDNS) of children aged 1½-4½ years,<sup>12</sup> people aged 65 years and over,<sup>13</sup> and young people aged 4-18 years.<sup>14</sup> Further revisions and updates were carried out by the Food Standards Agency (FSA) for the NDNS of adults aged 19 to 64 years.<sup>15</sup> It was revised again by nutritionists at KCL for LIDNS<sup>2</sup>. See Appendix A for further details.

## **2.4 Data handling**

### ***2.4.1 Defining age for data collection***

Children were selected for inclusion in this survey based on their age on 1<sup>st</sup> May 2006. All those aged between 3 and 16 years on this date were eligible for selection. Interviews were conducted over a period of three and a half months, from mid May until early September 2006. At the time of interview a number of children had reached their next birthday. Analysis of response rates (Chapter 3) uses the age of the children at sampling. However, due to the need to compare information on diet and height and weight with age-specific reference data, all other analyses in the report use the age at the interview.

Twenty-one FFQs were returned for which there was no corresponding face to face interview. For these 21 respondents, it was possible to determine their age group at interview (3-7, 8-11 or 12-17) from their date of birth and assuming that FFQs were completed during the period of interview (May to September 2006).

### ***2.4.2 Exclusions based on dietary data***

Current standard operating procedures for the SCG FFQ recommend that nutrient data is not produced for FFQs containing more than 10 missed lines. For all FFQs for which nutrient data was not produced, the FFQ was checked to ensure that it contained more than 10 blank lines, and that the FFQ was not excluded due to a data entry error. Of 1512 respondents who returned an FFQ, 51 (3%) had missed more than 10 lines, and were therefore excluded from the dietary analysis.

It is recognised that food frequency questionnaire data is likely to include some results with implausibly high or low nutrient intakes and has been suggested that total energy intake may be used as the primary criterion for exclusion<sup>16</sup>. There are no agreed cut-offs for exclusion of FFQs on the basis of energy intake so for this survey the Standard Operating Procedure for the Scottish Collaborative Group of removing the participants with energy above the 97.5th centile or below the 2.5th centile of the distribution of energy in the three age-groups was used.

Of the 1461 respondents who had not missed more than 10 lines on the FFQ, 70 (5%) with extreme total energy intakes (<2.5th centile or >97.5th centile for each age group (3-7, 8-11 or 12-17 years at the interview)) were further excluded from the dietary analysis. These exclusions are also in line with current standard operating procedures for the FFQ.

Of 195 diet diaries that were returned, 42 (22%) were excluded from the comparison with the FFQ: nine diet diaries (5%) were incomplete; nine (5%) contained no identification number and therefore could not be matched with the corresponding FFQ; there was no FFQ with a

corresponding ID for eight diet diaries (4%); 11 (6%) corresponding FFQs had more than 10 blank lines; and five (3%) FFQs had extreme total energy intakes. Of the 424 24-hour recalls that were completed, only one (0.2%) was excluded from the comparison with the FFQ as no foods had been consumed.

## **2.5 Data analysis**

Data analysis was carried out using SPSS version 12<sup>17</sup> and Stata/SE9.2<sup>18</sup>.

### **2.5.1 Weighting**

The data was weighted so that the estimates generated from the responding sample more accurately reflect the characteristics of the population of children aged 3-16 on 1st May, 2006 in Scotland. Weights were calculated to take account of selection and non-response bias and then these composite weights were adjusted to create a calibration weight (Appendix A).

### **2.5.2 Food energy versus total energy**

Intakes of macronutrients are expressed as a percentage of food energy. In this survey, the percentage of food energy is likely to be very similar to the percentage of total energy, since alcohol (which accounts for the difference between food and total energy), contributed less than 1% of energy intake in all children. Food energy was calculated as [total energy (kJ) - (alcohol (g) x 29kJ)]. Intakes of macronutrients expressed as a percentage of food energy were calculated using the factors of 16kJ per gram for total sugars, NMES, intrinsic and milk sugars and carbohydrate; 37kJ per gram for total fat and saturated fatty acids; and 17kJ per gram for protein.

### **2.5.3 Comparison of methods of dietary assessment**

Weightings were not applied in the comparison of methods as the purpose of this analysis was to compare nutrient intakes obtained by different methods in the same subjects.

Differences in characteristics (age group, sex and SIMD quintile) between respondents who completed an FFQ only, both a diet diary and FFQ, or both a 24h recall and FFQ were assessed using a Pearson chi-square test.

Differences in nutrient intakes between the FFQ and diet diary and between the FFQ and 24h recall were assessed using the Wilcoxon signed-rank test when the nutrient intake from either dietary assessment method was not normally distributed. A paired t-test was used to test for differences between methods when nutrient intakes from both methods were normally distributed.

For each nutrient, the log percent difference between methods was calculated as a measure of difference in the estimates of nutrient intake between two methods: log percent difference =  $[\ln(\text{nutrient intake from FFQ}) - \ln(\text{nutrient intake from diet diary or 24h recall})] \times 100$ . The log percent difference does not presume that one or the other measure is the standard, as opposed to methods which may use the diary or FFQ as the reference method.

#### **2.5.4 Classification of overweight and obese**

Body mass index (BMI) and BMI z-score were determined using the lmsGrowth program version 2.09<sup>19</sup>. BMI was calculated as weight (kg) divided by height (m<sup>2</sup>). Respondents were classified as follows:

- underweight: BMI  $\leq 5^{\text{th}}$  centile of the UK 1990 reference data (z-score  $\leq -1.64$ )
- overweight but not obese: BMI  $\geq 85^{\text{th}}$  centile and  $< 95^{\text{th}}$  centile (z-score  $\geq 1.04$  and  $< 1.64$ )
- obese: BMI  $\geq 95^{\text{th}}$  centile (z-score  $\geq 1.64$ )

#### **2.5.5 Deviations from the normal distribution**

All continuous variables were tested for deviations from the normal distribution, and variables which were significantly skewed were transformed as described below. Therefore, the means presented in this report are not influenced by skewed data. In addition, transformation of data to achieve normality was necessary to allow statistical testing of associations between diet and demographic and health variables.

Intakes of food groups and nutrients, the percentage contribution of food groups to nutrient intake, height, weight, BMI and BMI z-scores were tested for normality based on tests for skewness and kurtosis which were then combined into an overall test statistic. Variables which were significantly skewed were transformed into a new variable  $\ln(+/-(\text{old variable}) - k)$ , choosing  $k$  and the sign of (old variable) so that the skewness of the new variable was zero. Means and 95% confidence limits of the transformed variables were then converted back to the original scale.

#### **2.5.6 Tests of association**

Associations between the percentages of children with a specified characteristic (consumers of foods groups, taking supplements, responding to height and weight measures, classified as overweight/obese, time spent participating in physical activity, time spent sitting at a screen, meeting current physical activity recommendations, ever attended a dentist, reason for first attendance, type of dental treatment), and sex, age group, SIMD quintile, urban/rural classification, or BMI classification were assessed using the Pearson chi-squared statistic which was then corrected for the survey design using the second-order correction of Rao and Scott<sup>20</sup> and converted into an F-statistic.

Differences between sexes in means of continuous variables (intakes of food groups or nutrients, the percentage contribution of food groups to nutrient intake, height, weight, BMI, BMI z-score, time spent participating in physical activities, time spent sitting at a screen, age of first attendance at a dentist) were assessed by t-test. Similarly, differences in mean intakes of nutrients and food groups between children who had never been treated for decay and children who had been treated for decay were also assessed by t-test.

Overall associations between continuous variables and age group, SIMD quintile, urban/rural classification, or BMI classification were assessed by an adjusted Wald test. The adjusted Wald test was used within regression analyses using the Stata *testparm* command which tests whether the value for all levels of the categorical variable (i.e. age group, SIMD etc.) are equal in a single test, and produces a single p-value.

Linear associations between continuous variables and age group, SIMD quintile or BMI classification were assessed by linear regression.

### **2.5.7 Scottish Index of Multiple Deprivation**

Data in this survey was also analysed by the Scottish Index of Multiple Deprivation<sup>21</sup> (SIMD). This index identifies small area concentrations of multiple deprivation across all of Scotland in a fair way.

The SIMD is made up of a series of different domains each consisting of a number of indicators chosen to efficiently capture deprivation for that domain area. The domains for the 2006 SIMD, used in this survey, are: Current Income, Employment, Housing, Health, Education, Geographic Access to Services and Crime. Also included in the 2006 SIMD is a new public transport sub-domain in the Geographic Access to Services domain

The SIMD is presented at Data Zone level, enabling small pockets of deprivation to be identified. The data zones, which have a median population size of 769, are ranked from most deprived (1) to least deprived (6,505) on the overall SIMD and on each of the individual domains. The result is a comprehensive picture of relative area deprivation across Scotland.

For the purposes of this report, the full index has been separated into quintiles and each case has been assigned a quintile based on the residential postcode. Quintiles are percentiles which divide a distribution into fifths, i.e., the 20th, 40th, 60th, and 80th percentiles. For example, those respondents whose postcode falls into the first quintile are said to live in one of the 20% least deprived areas in Scotland. Those whose postcode falls into the fifth quintile are said to live in one of the 20% most deprived areas in Scotland.

### **2.5.8 Scottish Executive Urban Rural Classification**

Data was also analysed using the Scottish Executive Urban Rural Classification<sup>22</sup>. The classification distinguishes between urban, rural and remote areas within Scotland. It is consistent with the Executive's core definition of rurality which defines settlements of 3,000 or less people to be rural. It also classifies areas as remote based on drive times from settlements of 10,000 or more people.

The classification used in this report includes the following categories:

**Table 2.1. Scottish Executive Urban Rural Classification**

<b>Scottish Executive Urban Rural Classification</b>	
1. Large Urban Areas	Settlements of over 125,000 people
2. Other Urban Areas	Settlements of 10,000 to 125,000 people
3. Accessible Small Towns	Settlements of between 3,000 and 10,000 people and within 30 minutes drive of a settlement of 10,000 or more
4. Remote Small Towns	Settlements of between 3,000 and 10,000 people and with a drive time of over 30 minutes to a settlement of 10,000 or more
5. Accessible Rural	Settlements of less than 3,000 people and within 30 minutes drive of a settlement of 10,000 or more
6. Remote Rural	Settlements of less than 3,000 people and with a drive time of over 30 minutes to a settlement of 10,000 or more

## **2.6 Ethical Approval**

This study did not require access to health records or any data held by the National Health Service, therefore ethical approval was not required. The secretary of the Multi Centre

Research Ethics Committee in Edinburgh confirmed that ethical approval was not required for this study.

### 3 RESPONSE

The survey comprised two components; a self completion FFQ and a face to face interview. In addition two different sub-samples of the main sample were asked to take part in further elements of the study: completion of a 4 day diet diary or completion of the 24-hour recall.

This section looks firstly at the response to the FFQ and face to face interview for the main sample and secondly examines the response to the 4 day diet diary and 24-hour recall by the two sub-samples. Finally, the effect of using the two different levels of incentive on response rate is presented.

The age of the child at sampling, as opposed to age at interview, is used throughout this chapter.

#### 3.1 Response rates

##### 3.1.1 Whole sample

Interviews were carried out with a total of 1700 children or parents/guardians of children for those under 12 years of age. Of those completing a face to face interview, 1491 also completed and returned an FFQ. A further 21 FFQs were returned for which there was no corresponding face to face interview.

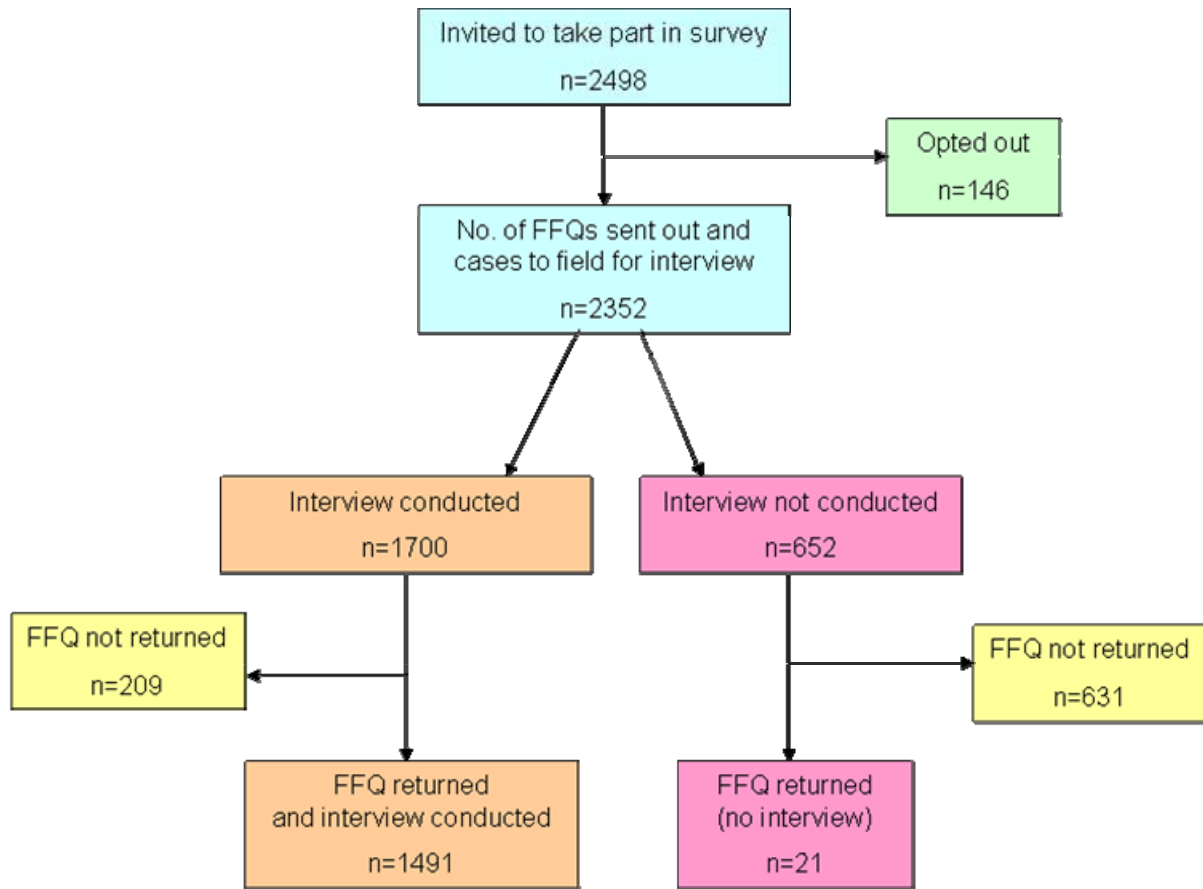

In addition, 9 FFQs were returned with no serial number to identify the respondent which would allow matching with the interview data and another was returned outside the data collection period. The data from these interviews could not be used in the analysis.

As there were several possible outcomes for this survey (see Fig 3.1), a range of response rates are presented. This includes separate response rates for interviews achieved and for FFQs returned, in addition to a response rate for those who completed both these components of the survey.

#### Table 3.1, Figure 3.1

The response rates presented in Table 3.1 assume that all those who could not be contacted were not eligible to be included in the survey. The response rates were therefore calculated on a base of 2245 i.e. all those considered 'in scope'. It is likely that a proportion of these potential respondents who could not be contacted would have been eligible, but there is no way of estimating how many. If all are assumed to be eligible to take part in the study the base on which response rates are calculated would be 2464. Using this as the base a more conservative estimate of the response rate for those responding to both components of the survey would be 60%. Similarly more conservative response rates for completion of the FFQ alone and for the interview alone would be 61% and 69% respectively. It is likely that the true response rates for each component of the study lies somewhere between these two extremes.

**Figure 3.1 Possible response outcomes**

**Response by age and sex**

It is important to note that as outlined in Section 2.2, a parent or guardian was asked to respond for those children in the sample under 12 years of age. Those aged 12 years and over were asked to complete the FFQ themselves with help from parents and respond to questions on physical activity and dental health in the face to face interview. A parent or guardian was asked to respond to the socioeconomic questions. Completion of the interview for those aged 12-16 years therefore required input from both adult and child.

There was a significant overall association between response rate for all components of the survey and age group. The highest response rates for all components of the main survey were achieved for the middle age group, 8-11 year olds. This was true for both sexes. Response to the combined interview and FFQ was significantly associated with age group in boys but not girls. Boys in the oldest age group were less likely to respond than those in the youngest age group. However, response rates were similar for the oldest and youngest girls.

There were no significant differences in response rates between the sexes.

**Table 3.2**

**Age and sex profile of the whole sample**

Table 3.3 compares the age and sex profile of participants responding to the different components of the survey to the mid year 2005 population estimates for Scotland.<sup>1</sup>

The proportion of boys aged 3-7 years responding to each component was comparable to the population estimates for the same age group. Girls in this age group were slightly under represented.

The middle age group, 8-11 year olds, is over represented in the sample whilst the oldest age group is under represented relative to their proportions in the population estimates. This is true for both sexes and all components of the survey.

Overall the proportions of boys to girls in the sample are the same as in the population estimates: 51% boys and 49% girls in both responding sample and population estimate.

**Table 3.3**

### ***Response by Scottish Index of Multiple Deprivation (SIMD)***

There was a significant association between SIMD and the response rate to the combined interview and FFQ and the FFQ alone. Those in the 1<sup>st</sup> quintile (least deprived) were most likely to take part in the survey; those in the 5<sup>th</sup> quintile (most deprived) were least likely to take part. There was a difference of 13 percentage points for those responding to the FFQ (71% vs.58%) and the combined FFQ and interview (71% vs.58%). Those in the 5<sup>th</sup> quintile were much less likely to complete and return the FFQ than those in the 1<sup>st</sup> quintile. There was no significant difference in response rates to the interview component of the survey by SIMD.

**Table 3.4**

### ***Response to physical measurements***

All those taking part in a face to face interview were invited to have their height and weight measured. There was a high level of co-operation from respondents to this element of the survey. Height measurements were taken for 96% of respondents and weight measurements for 96% of respondents.

**Table 3.5**

There was a significant association between the agreement to height and weight measurements and SIMD. Those in the most deprived quintile were least likely to have provided height and weight measurements compared with those in other SIMD quintiles.

**Table 3.6**

### ***3.1.2 Sub-samples***

During the course of the face to face interview, randomly selected respondents were asked to complete a 4 day diet diary or to complete a single 24-hour recall.

In the first sub-sample, respondents were asked if they would be willing to complete the 4 day diet diary and post it back to the researchers. An incentive was offered to those who agreed to complete this additional component. Of the 311 respondents asked, 309 (99%) agreed to complete the diet diary. A total of 186 diaries (60%) were returned. In addition another 9 diaries were returned with no means of identification so could not be included as valid returns.

Of the 429 respondents who were asked to complete the 24-hour recall, 424 (99%) did so. There were very few refusals in this additional component once the respondent had begun the interview.

The table below shows the distribution of days of the week for the 423 respondents for which complete 24-hour recall data were available. The ratio of weekend days to weekdays is 0.33 (the ideal balance is 0.4 or 2:5). Fewer 24-hour recalls were carried out for Fridays and Saturdays (i.e. there were fewer interviews carried out at the weekend) and a higher proportion for Sundays and Mondays.

**Proportion of 24-hour recalls conducted by day of week**

Monday	Tuesday	Wednesday	Thursday	Friday	Saturday	Sunday
%	%	%	%	%	%	%
23	18	18	14	2	3	22

**Table 3.7, Table 3.8**

**Response by age and sex for sub-samples**

The response rate to completing the 24-hour recall was similar to that of completing the main interview and FFQ. This is not surprising as the 24-hour recall followed immediately after the main interview, thus having agreed to the first part of the interview respondents were likely to respond positively to the second part.

There was a significant association between completing the 24-hour recall and age group overall and for girls. The 24-hour recall was more likely to be completed for the middle age group than for the youngest and oldest age groups overall and for girls.

Returns of the completed diet diary showed a similar pattern of response although overall response rates were lower. No significant association was found between age group and completion of the diet diary.

**Table 3.9**

**Response by SIMD for sub-samples**

Response to completing the 24-hour recall and returning the 4 day diet diary showed a similar pattern of response to the whole sample. Those in the 1<sup>st</sup> quintile (least deprived) were more likely to respond than those in the 5<sup>th</sup> quintile (most deprived). However only the response to completing the diary was significantly related to SIMD. Over a half of those (56%) in the 1<sup>st</sup> quintile returned a completed diet diary compared to less than a third (31%) of those in the 5<sup>th</sup> quintile.

**Table 3.10**

**3.2 Incentives**

The survey incorporated an incentive experiment to examine the effect of two different levels of incentives on the response rate for those completing the FFQ and taking part in the face to face interview. This section presents the findings of this experiment.

Participants were split at random into two groups: one group received a £1 high street voucher while the other received a £5 voucher. The incentives were unconditional and were sent out with the letter and FFQ in advance of the interviewer calling to conduct the interview.

To control for interviewer effect, interviewers were not told how the incentives were being distributed among participants so they were not aware, in advance, of who received which value of incentive. Each interviewer had participants receiving different levels of incentive.

Overall, the higher level of incentive was associated with an increase in the response rate of 5-7 percentage points to each component of the main survey. The increase was statistically significant for all components of the survey.

Amongst boys, response rates of those receiving the higher incentive were 6-7 percentage points higher for all components of the survey compared to those receiving the lower level. These differences were all significant. Amongst girls the differences in response rates were significant only for those completing the FFQ alone and the combined interview and FFQ. Response rates for those completing the FFQ alone and FFQ plus interview were 7 and 8 percentage points higher respectively for girls receiving the higher level incentive than those receiving the lower level.

Examination of response rates by level of incentive and age group indicates that response rates were higher for the higher level of incentive for all components of the survey in all age groups. The differences in response were either statistically significant or of borderline significance.

## 4 COMPARISON OF METHODS OF DIETARY ASSESSMENT

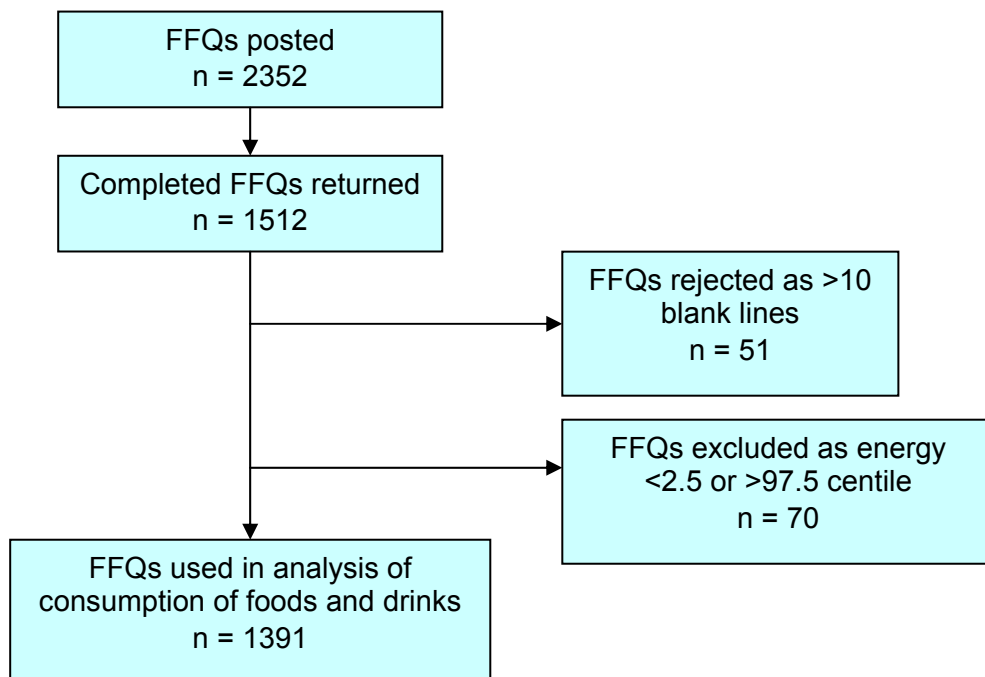

The methods used in the assessment of diet by FFQ, diet diary and 24-hour recall were described in Section 2.3 which also outlined the rationale for the choice of these methods. Completion of the different methods was discussed in Section 2.3. This chapter presents a comparison of the characteristics of the participants who completed the different dietary assessment methods and compares the nutrient intake for those participants who provided data by the FFQ and either the diet diary or the 24-hour recall.

### 4.1 Characteristics of participants who provided data by the different dietary assessment methods

A total of 1512 FFQs were returned. After exclusion of outliers and incomplete questionnaires, (see Section 2.4.2 for further details) 1,391 FFQs were available for analysis of nutrient intake (see Figure 4.1)

Figure 4.1

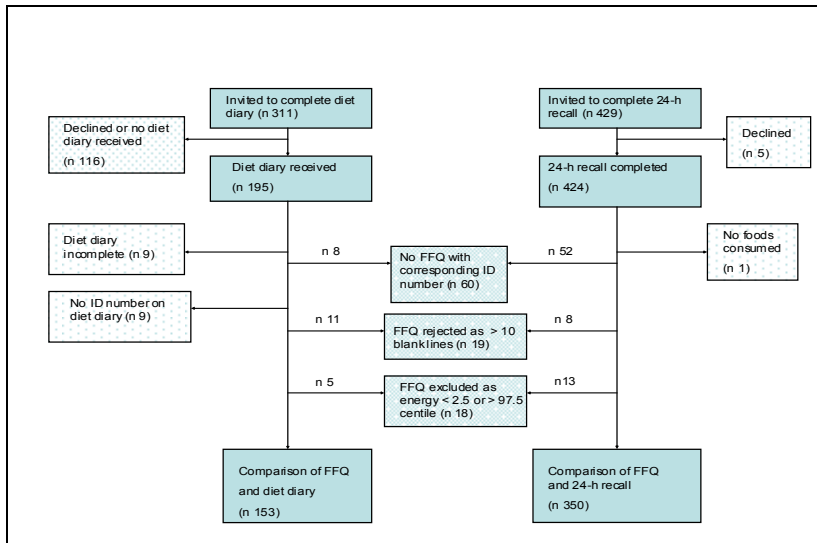

Figure 4.1 Number of FFQs used in the analysis of consumption of food and drinks

Details of the process by which the final samples for comparison of FFQ with diet diary or FFQ with 24-hour recall were derived are shown in Figure 4.2. (See Section 2.4.2 for further details). Comparison of nutrient intake as recorded by FFQ and diet diary was carried out for 153 participants while comparison of nutrient intake by FFQ and 24-hour recall was carried out for 350 participants.

Figure 4.2

**Figure 4.2 Development of samples for comparison of FFQ with diet diary or 24-hour recall**

The characteristics of the participants who completed the FFQ only, those who were included in the comparison of the FFQ and diet diary and those who were included in the comparison of the FFQ and 24-hour recall are shown in Table 4.1. The age and sex distribution was similar in all three groups.

Among the participants who completed the FFQ and diet diaries those in the most deprived quintile were under-represented but among the participants who completed the FFQ and 24-hour recall those in the most deprived quintile were over-represented.

Comparison with the age and sex distribution for the estimated mid year population for 2005 shows that the sample completing the various combinations of the survey components closely resembled the sex and age breakdown of the population as a whole. The youngest age group was slightly under represented for the FFQ only and the combined FFQ and diet diary but were very close to the population for the combined FFQ and 24-hour recall, whilst the middle age group were over represented and the oldest age group under represented.

**Table 4.1**

## 4.2 Comparison of nutrient intake by FFQ and diet diary

There is no established level of acceptable agreement between two dietary methods but perfect agreement is not expected when the time period covered differs between the methods, as the comparison will be affected by intra-individual variation in diet with time. For this survey an arbitrary value of 5% or less was used for good agreement between the methods while 20% or more was considered to show poor agreement.

Table 4.2 shows the energy and nutrient intakes for the 153 participants who completed the FFQ and diet diary. For participants overall, the energy intake was reported to be significantly higher using the FFQ than using the diet diary. The reported energy intake using the FFQ was also significantly higher than that reported using the diet diary for those aged 3-11 years but there was no significant difference in the energy intake by the two methods for those aged 12-17 years.

**Table 4.2**

For all participants the nutrient intakes expressed as a percentage of food energy were significantly higher as recorded by the FFQ than the diet diary for total sugars, intrinsic and milk sugars, sucrose and carbohydrate and significantly lower for protein. There was no significant difference in the percentage of food energy between the two methods for NMES, total fat and saturated fatty acids.

The pattern was very similar in those aged 3-11 years and those aged 12-17 years with no significant difference between the intake of NMES as a percentage of food energy between the FFQ and diet diary for either age group.

For all participants the absolute intakes of all macronutrients apart from protein and of iron and calcium were significantly higher as recorded by the FFQ than the diet diary with the median log percentage differences ranging from 7.5% for saturated fatty acids to 37.3% for intrinsic and milk sugars.

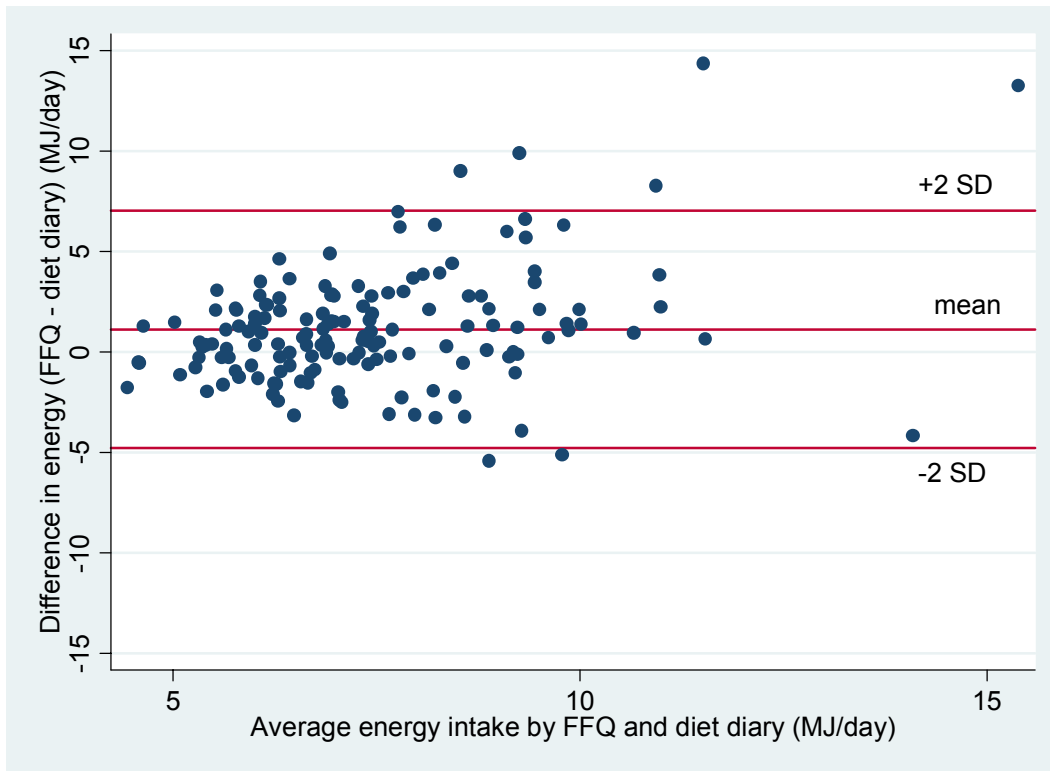

For those aged 3-11 years the absolute macronutrient intakes were significantly higher as recorded by the FFQ than the diet diary for all reported nutrients. In the 12-17 year olds the absolute nutrient intakes were significantly higher as recorded by the FFQ than the diet diary for total sugars, intrinsic and milk sugars, sucrose and non-starch polysaccharides but were not significantly different for NMES, total fat, saturated fatty acids, carbohydrate, protein, iron and calcium.

In all participants the absolute intakes of folate, vitamin C and retinol equivalents were 30.9%, 49.6% and 27.8% higher respectively as recorded by the FFQ than the diet diary (all  $p < 0.001$ ). This was consistent with the fact that the weight of vegetables and fruit consumed per day by consumers in the FFQ was more than 60% higher than the weight recorded per day in the diet diary. As a result, the intakes of folate, vitamin C and retinol equivalents from the FFQ were considered to be unreliable and are not presented in this report. Over-estimation of the amount of fruit and vegetables in the FFQ could explain the fact that the NSP intake recorded on the FFQ was 27.2% higher than in the diet diary (see Table 4.2).

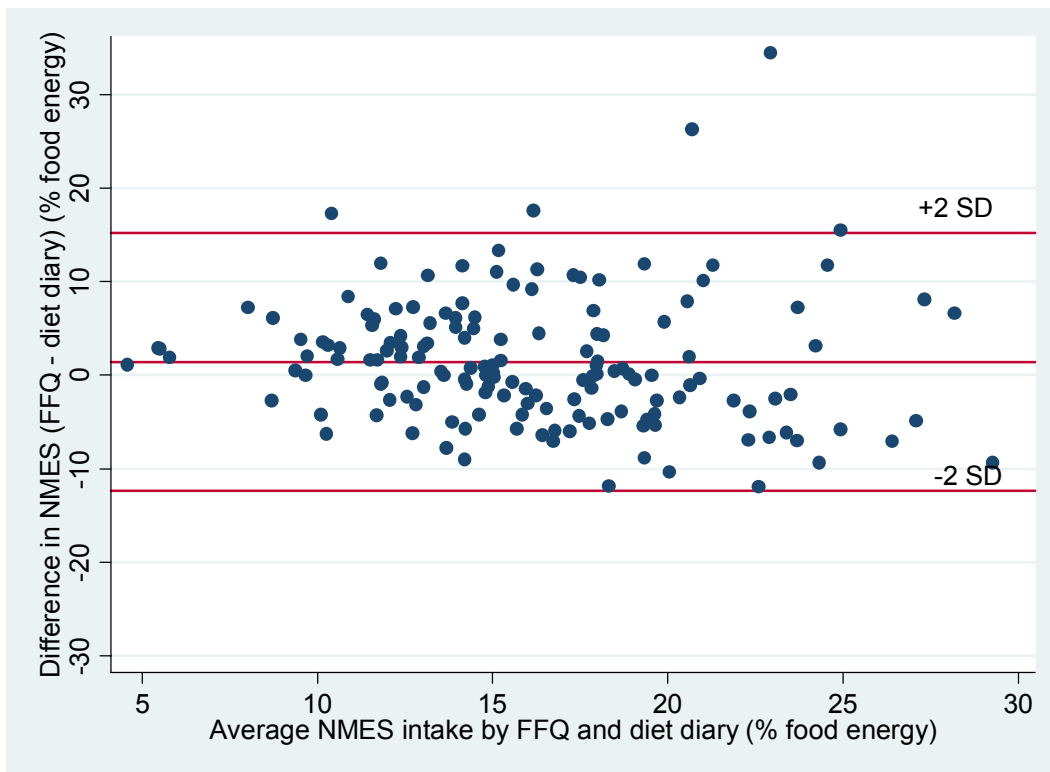

Figure 4.3 and Figure 4.4 show 'Bland and Altman'<sup>1</sup> plots of the values for energy intake and NMES as a % of food energy, respectively for the 153 participants who completed the FFQ and diet diary. These plots illustrate the wide range of individual differences within 95% confidence limits with agreements for individual values being approximately  $\pm 6$  MJ/d for energy intake and  $\pm 14\%$  NMES as a percentage of food energy.

**Figure 4.3, Figure 4.4**

**Figure 4.3** Bland and Altman plot for energy intake by FFQ and diet diary

**Figure 4.4** Bland and Altman plot for NMES (% food energy) by FFQ and diet diary

### 4.3 Comparison of nutrient intake by FFQ and 24-hour recall

The energy and nutrient intakes in the 350 participants who completed both the FFQ and 24-hour recall are shown in Table 4.3. Overall, the energy intake was significantly higher as recorded with the FFQ than with the 24-hour recall.

In those aged 3-11 years the energy intake was significantly higher as recorded with the FFQ than with the 24-hour recall. In contrast amongst the 12-17 year olds the energy intake was lower with the FFQ than the 24-hour recall though the difference was not statistically significant. The median log percentage difference in energy intake between the FFQ and 24-hour recall was 4.5% in boys and 7.8% in girls (table not shown).

**Table 4.3**

For all participants, the nutrient intake expressed as a percentage of food energy was significantly higher by the FFQ than the 24-hour recall for total sugars, NMES, intrinsic and milk sugars, sucrose and carbohydrate and significantly lower for protein. There were no significant differences for intake of total fat or saturated fatty acids as a percentage of food energy between the two methods.

In 3-11 year olds the intakes of total sugars, intrinsic and milk sugars and sucrose as a percentage of food energy were significantly higher by the FFQ than the 24-hour recall but the intake of protein was significantly lower. There was no significant difference between the two methods in the intake of NMES, total fat or saturated fatty acids as a percentage of food energy. In the 12-17 year olds the intakes of total sugars, NMES, intrinsic and milk sugars, sucrose and carbohydrate as a percentage of food energy were significantly higher by the FFQ than the 24-hour recall but the intake of total fat and protein were significantly lower. There was no significant difference in the intake of saturated fatty acids as a percentage of food energy between the two methods.

In all participants the absolute intake of all reported nutrients apart from total fat, protein and iron were significantly higher as recorded by the FFQ than the 24-hour recall with the median log percentage differences ranging from 9.6% for carbohydrate to 34.7% for intrinsic and milk sugars.

In those aged 3-11 years the absolute intakes of all reported nutrients were significantly higher as recorded by the FFQ than the 24-hour recall. Absolute nutrient intakes recorded by the FFQ were significantly higher for those aged 12-17 years than those recorded by the 24-hour recall for total sugars, NMES, intrinsic and milk sugars, sucrose and calcium and significantly lower for protein. The differences between the two methods were not statistically significant for total fat, saturated fatty acids, carbohydrate and iron.

### 4.4 Discussion

In the comparison of different methods of dietary assessment, perfect agreement is unlikely for a variety of reasons. The three methods used here present different challenges for the respondents which may each introduce error. The FFQ requires respondents to categorise foods and to estimate the frequency of consumption of a large list of foods. This may be difficult particularly for foods which are eaten infrequently. The diet diary is labour-intensive and may, as a result, encourage under-eating and/or under-recording of food eaten. The 24-hour recall is less time-consuming for the respondents but relies on the accuracy of recall of the variety and amount of foods consumed. In addition the three methods collect information for different time periods: the FFQ enquires about usual diet while the diet diary and 24-hour

recall give more precise information on a smaller number of days. Since energy and nutrient intake varies from day to day within individuals, if the days selected for measurement are not representative of long-term dietary habits the short-term methods may not reflect habitual diet.

One possible explanation for the difference in energy and absolute nutrient intakes between the FFQ and diet diary is under-reporting of energy intake in diet diaries. This is well-documented in adults and has also been reported in children.<sup>2</sup> This is supported by the fact that the median log percentage difference for energy intake between the FFQ and 24-hour recall was less than that for the FFQ and diet diaries. However, over-estimation when using FFQs is also common, particularly in those FFQs with longer food lists<sup>3</sup>, which could also have contributed to the differences observed between the methods. The overestimation of energy and absolute nutrient intakes by the FFQ relative to both the diet diary and the 24-hour recall was seen more clearly in the 3-11 year olds than in the 12-17 year olds, which suggests a difference in reporting behaviour for the FFQ between parents or guardians and young people.

In the present study, the agreement between the FFQ and diet diaries for all participants was better for nutrient intakes expressed as a percentage of food energy than for absolute nutrient intakes for all the nutrients reported. As the median log percentage differences between the intake of NMES, total fat, saturated fatty acids and carbohydrate expressed as a percentage of food energy by the FFQ and diet diaries were under 5% in all participants it was concluded that the FFQ provided reasonable estimates of these variables. For other reported nutrients, particularly those in which the median log % difference between the FFQ and diet diaries and between the FFQ and 24-hour recall was 20% or more, such as intrinsic and milk sugars, intakes from the FFQ used in this survey should not be compared with data from other surveys using different methods.

## 5 INTAKE OF FOOD GROUPS AND SUPPLEMENTS

This chapter and the subsequent two chapters present data on food consumption, nutrient and energy intake and nutritional status based on information collected in the FFQs.

This chapter describes the consumption of foods and drinks for the 1,391 children for whom a valid FFQ was obtained (see Section 4.1) and the variation in consumption by age, sex, deprivation and urban/rural classification. The groupings of foods and drinks from the FFQ were based on that used in the Low Income Diet and Nutrition Survey<sup>1</sup> with some minor modifications required to allow for the grouping of foods in the FFQ. A full list of the food and drink groups as used for the FFQ is provided in Appendix A. The use of supplements is also described for all the 1512 children who returned an FFQ.

### Notes on tables:

1. 'Consumers' are defined as children who reported consuming one or more items from the food and drink groups listed on the FFQ at least once a month. The amounts consumed are calculated as the average daily amount for consumers only. The average amount for all children (including non-consumers) can be estimated as  $[(\text{amount consumed by consumers}) \times 100] / (\text{percentage of consumers})$ .

2. The actual values for the amounts of foods and drinks consumed are presented in this chapter to allow comparisons between subgroups, but must be interpreted in the light of possible over- or under-estimation by the FFQ, as discussed in Section 4.4. For this reason, the reported amounts of foods and drinks presented here should not be compared with those derived from other studies, or with food-based dietary recommendations such as the Scottish Dietary Targets for fruit and vegetables, bread, breakfast cereals, rice, pasta and fish (see Table 1.1).

3. Due to the transformations which were carried out for skewed data, the sum of the mean percentage contributions from all food groups to nutrient intake does not equal 100%. The percentage contribution of all food groups to energy, sugar and fat intake are presented as both transformed and untransformed data in appendix H.

### 5.1 Consumption of foods and drinks

Over 95% of children reported consuming the following foods at least once a month: pasta, rice and pizza; bread excluding wholemeal; biscuits, cakes and pastries; milk and cream; yoghurt and fromage frais; meat and meat dishes; processed meat; vegetables; chips; crisps and savoury snacks; fruit; confectionery and soups and sauces. 59% of children reported consuming wholemeal bread and 39% reported consuming oily fish and dishes at least once a month.

**Table 5.1**

#### 5.1.1 Consumption of foods and drinks by age

The influence of age on the proportion of children consuming specific groups of food or drinks was significant for wholemeal bread, unsweetened breakfast cereals, yoghurt and fromage frais, ice-cream, fats and oils and white fish, shellfish and fish dishes. Younger children were more likely to consume these foods than older

children. Chips and fried potatoes, other potatoes, nuts and seeds, non-diet soft drinks and powdered beverages were more likely to be consumed by older children than younger children.

**Tables 5.1, 5.1a**

The influence of age on the amounts of foods and drinks consumed was significant for many food or drink groups. Children in the youngest age group, 3-7 year olds, reported consuming more wholemeal bread, unsweetened breakfast cereals, milk and cream, cheese; yoghurt and fromage frais, fats and oils and fruit than older children. Consumption of crisps and savoury snacks was higher amongst the 8-11 year olds than either younger or older children. Those in the oldest age group, 12-17 year olds, consumed more confectionery, non-diet soft drinks and tea, coffee and water than younger children.

**Tables 5.1, 5.1b**

### **5.1.2 Consumption of foods and drinks by sex**

Differences between the sexes in the proportions of children consuming specific groups of foods or drinks was generally small. When the differences between sexes was statistically significant the proportion of girls consuming the food or drink was higher than the proportion of boys. The exception to this was sweetened cereals. The proportion of 12-17 year old boys consuming the food was significantly higher than the proportion of girls of the same age (71% vs. 58%).

**Tables 5.1, 5.1c**

The amounts of foods and drinks consumed by the consumers, , expressed as grams per day (g/d), were significantly higher in boys than girls for many food groups but particularly for unsweetened breakfast cereals, milk and cream and processed meat. However the consumption of vegetables and fruit was significantly higher in girls than boys (55 vs. 49 g/d and 141 vs. 125 g/d respectively).

**Tables 5.1, 5.1d**

### **5.1.3 Consumption of foods and drinks by Scottish Index of Multiple Deprivation**

There were significant associations between SIMD quintile and the proportion of children who consumed several groups of food or drink. The proportion consuming wholemeal bread, cheese, oily fish and fish dishes and fruit juice was lower among those living in more deprived areas. The proportion consuming diet soft drinks was higher among those living in more deprived areas.

There were more significant associations between SIMD quintile and the amounts of different foods and drink groups consumed by the consumers. The average daily amounts of pasta, rice and pizza, vegetables, fruit and fruit juice consumed were lower among those living in more deprived areas. The amounts of ice-cream, eggs, processed meat, chips, crisps, confectionery, non-diet and diet soft drinks were higher among those living in more deprived areas.

**Table 5.2**

### **5.1.4 Consumption of foods and drink by urban/rural classification**

The only significant association between urban/rural classification and the proportion of children consuming specific food groups was for the consumption of oily fish and dishes. A higher proportion of those living in remote small towns and remote rural areas reported they consumed oily fish and dishes than those living in other areas,

though data for those living in remote rural areas should be interpreted with care because of small bases.

There was a significant association between urban/rural classification and the intake of bread excluding wholemeal, milk and cream, vegetables, and crisps and savoury snacks among consumers. The intake of milk and cream and vegetables was highest among those living in remote small towns and remote rural areas whilst intake of bread excluding wholemeal and crisps and savoury snacks was lowest among those living in remote rural areas. As above, care must be used in interpreting these findings due to the small bases.

**Table 5.3**

## **5.2 Consumption of alcoholic drinks**

Information on the consumption of alcoholic drinks was only available for children aged 12-17 years who completed the C3 FFQ as the C2 FFQ for children aged 11 and under did not include alcoholic drinks.

16% of those children who completed the C3 FFQ reported consuming alcoholic drinks at least once a month.

**Table 5.4**

### **5.2.1 Consumption of alcoholic drinks by sex**

Girls were significantly more likely to report consuming alcohol than boys (20% vs. 12%). However, reported mean intake of alcoholic drinks was higher amongst boys than girls (45 g/d vs. 27 g/d) although a statistical test for the difference was not carried out due to the small bases.

**Table 5.4**

### **5.2.2 Consumption of alcoholic drinks by Scottish Index of Multiple Deprivation and urban/rural classification**

There was no significant association between SIMD quintile and the proportion of children who reported consuming alcohol. The reported amount of alcohol consumed among consumers was highest in the most deprived (5<sup>th</sup>) quintile (61 grams/day) although some bases were small.

The proportion of children who reported consuming alcohol was highest in the remote rural areas (33%), however the bases were small for accessible and remote small towns and remote rural areas, therefore caution must be exercised when interpreting this data and the reported mean intakes.

**Table 5.5, Table 5.6**

## **5.3 Use of supplements**

In this section all 1512 FFQs returned (including 51 rejected as having more than 10 blank lines and 70 with very high or very low energy intake: see Figure 4.1) were used in the analysis of the use of supplements since neither of these factors were thought likely to affect reporting of supplement use.

Almost a quarter (23%) of those children for whom an FFQ was returned reported taking one or more supplements. Multivitamins and cod-liver oil were the most common types of supplements taken and were taken by 12% and 9% of children respectively.

### **5.3.1 Use of supplements by age and sex**

There was a significant influence of age on the proportion of children who were reported to be taking supplements. Those aged 3-7 years were the most likely to be taking 'any supplement' (29%), cod-liver oil and other fish based supplement (12%) or multivitamins (18%). Those aged 12-17 years were least likely to report taking any supplements apart from multivitamins and minerals.

Boys were significantly more likely than girls to report taking 'any supplement' (26% vs.20%) or cod-liver and other fish based oil (11% vs.7%).

**Tables 5.7, 5.7a, 5.7b**

### **5.3.2 Use of supplements by Scottish Index of Multiple Deprivation**

There was a significant association between SIMD quintile and the proportions of children taking supplements. Those in more deprived areas were less likely to report taking 'any supplement' than those in less deprived areas. The proportion of children who reported taking vitamins with minerals was also significantly different between the SIMD quintiles. Those in both the least and the most deprived quintiles were less likely to report taking this type of supplement than those in the other quintiles.

**Table 5.8**

### **5.3.3 Use of supplements by urban/rural classification**

There was no significant relationship between urban/rural classification and the likelihood of taking 'any supplement' but there was a significant relationship between urban/rural classification and the likelihood of taking vitamins with minerals. Those living in remote rural areas were more likely to report taking these supplements than those in other areas, particularly the large urban areas.

**Table 5.9**

## 6 INTAKE OF ENERGY, TOTAL SUGARS AND NMES

This chapter describes the intake of energy and sugars in all children and variations by age, sex, deprivation and urban-rural residence are also reported. Intakes are also compared to Dietary Reference Values and Scottish Dietary Targets. The definition of the different classes of sugars is given in Chapter 1 (Section 1.2) while the validity of the estimates of energy and sugars intake based on data collected in the FFQ is discussed in Chapter 4 (Section 4.4). The full list of the food groups and their contribution to energy, total sugar and NMES intake are given in Appendix H.

### 6.1 Intake of energy and sugars

#### 6.1.1 Intake of energy and sugars by age and sex

The intake of energy and sugars for all children and by sex and age is shown in Table 6.1. Statistical significance of differences in intake are shown in Tables 6.1a and 6.1b.

Boys had a significantly higher energy intake than girls overall and in those aged 8-11 years and 12-17 years. There was a significant increase in energy intake with age group in boys but not in girls. However, comparison between children under 11 years and those 12 years and over should take account of the fact that the C2 FFQ, used for children aged 3-11 years and designed for completion by parents, overestimated energy intake compared to that recorded in the diet diaries to a greater extent than the C3 FFQ used for young people aged 12-17 years which was designed for completion by the young people themselves (see Section 4.2).

Total sugars contributed on average 28.9% to food energy intake in children overall. There was a higher percentage contribution of total sugars to food energy intake amongst those aged 12-17 years (29.6%) compared to younger age groups (3-7 year olds, 28.6%, 8-11 year olds, 28.4%). This linear association between total sugars and age group was significant in girls but not in boys.

NMES contributed on average 17.4% to food energy intake in children overall and there was a highly significant increase in the percentage contribution with age group: in 3-7 year olds the mean percentage contribution was 15.8% while in 12-17 year olds the mean percentage contribution was 19.1%.

Intrinsic and milk sugars contributed on average 10.5% to food energy in children overall and there was a highly significant association with age group in the opposite direction to that seen for NMES: the mean percentage of food energy from intrinsic and milk sugars was 11.9% in the 3-7 year olds and 9.4% in the 12-17 year olds.

Sucrose contributed on average 13.4% to food energy in all children and the percentage contribution increased significantly with age group similar to the increase with age group seen for NMES.

There were no significant differences between boys and girls in the percentage contribution of the sugars to food energy intake.

When expressed as grams per day (g/d), the intake of total sugars, NMES and sucrose were significantly higher in boys than girls. The patterns of associations with

age group for NMES, intrinsic and milk sugars and sucrose expressed as g/d were similar to those seen for percentage food energy. For total sugars the mean intake in all children was 138 g/d but intake increased with age in boys only.

**Table 6.1, 6.1a, 6.1b**

Tables 6.2, 6.2a, 6.2b show similar analyses for NMES, intrinsic and milk sugars and sucrose expressed as a percentage of total sugars intake. In all children NMES contributed on average 61.8% and intrinsic and milk sugars contributed 38.2% to total sugars intake. The mean contribution of sucrose to total sugars intake was 46.9%. There were no significant differences between boys and girls in these values but there were highly significant associations with the age groups. The contribution of NMES and sucrose were higher and the contribution of intrinsic and milk sugars lower in the older children.

**Table 6.2, 6.2a and 6.2b**

**6.1.2 Intake of energy and sugars by Scottish Index of Multiple Deprivation**

Intake of energy and sugars by SIMD quintile is shown in Table 6.3. There was a significant association between energy intake and SIMD quintile with higher energy intake associated with increasing deprivation. There was no significant association between the SIMD quintiles and the percentage of food energy from total sugars but there were significant associations with the intake of NMES, intrinsic and milk sugars and sucrose. NMES and sucrose contributed a higher proportion of food energy and intrinsic and milk sugars contributed a lower proportion of food energy in the more deprived quintiles.

A similar pattern was seen for sugars expressed as g/d, though the intake of total sugars was significantly higher in the more deprived groups. The intake of intrinsic and milk sugars was not significantly associated with SIMD quintiles.

**Table 6.3**

When intakes of NMES, intrinsic and milk sugars and sucrose were expressed as a percentage of total sugars, highly significant linear associations with deprivation quintiles were observed. NMES and sucrose comprised a higher proportion of total sugars in the more deprived quintiles. In contrast, intrinsic and milk sugars comprised a lower proportion of total sugars in the more deprived quintiles.

**Table 6.4**

**6.1.3 Intake of energy and sugars by urban/rural classification**

Intake of energy and sugars by urban/rural area of residence is shown in Table 6.5. There were no significant associations between the areas of residence and energy intake or the percentage of energy from total sugars, NMES, intrinsic and milk sugars or sucrose. There were significant associations between the intake of total sugars and sucrose expressed as g/d and the areas of residence, with higher intakes in the remote small towns and lower intakes in the accessible small towns and accessible rural areas. There were no significant associations between the areas of residence and the percentage contribution of NMES, intrinsic and milk sugars or sucrose to total sugars intake.

**Table 6.5, Table 6.6**

## **6.2 Contribution of food groups to intake of energy and sugars**

Table 6.7 shows the mean percentage contribution of food groups contributing 5% or more to the intake of energy and sugars. The full list of the food groups and their contribution to energy, total sugar and NMES intake are given in Appendix H.

The food groups contributing the highest proportion of total energy intake were biscuits, cakes and pastries (9%) and bread excluding wholemeal (8%). Fruit (14%) and non-diet soft drinks (10%) were the food groups providing the highest proportion of total sugars. Non-diet soft drinks were also major contributors to NMES (17%), along with confectionery (12%) and biscuits, cakes and pastries (12%).

The main sources of NMES were similar to those in LIDNS and NDNS, though the contribution from table sugar and preserves was lower and the contribution from fruit juice (including smoothies) was higher than in the other surveys (see Appendix H).

Over half (56%) of intrinsic and milk sugars were obtained from fruit (35%) and milk and cream (21%). The food groups providing the highest proportion of sucrose intake were biscuits, cakes and pastries (13%), confectionery (12%) and non-diet soft drinks (12%).

**Table 6.7**

### ***6.2.1 Contribution of food groups to intake of energy and sugars by age and sex***

The differences in the percentage contribution of food groups to energy and sugars intake between boys and girls were generally small. The exceptions to this were a lower contribution of milk and cream (19% girls, 22% boys) and a higher contribution of fruit (37% girls, 32% boys) to intrinsic and milk sugars intake in girls compared to boys.

There were several significant associations between the percentage contribution of food groups to energy and sugars intake and age group. There was a clear pattern of lower contributions from milk and cream, yogurt and fromage frais and fruit, and higher contributions from non-diet soft drinks and confectionery to total sugars, NMES and sucrose intake with increasing age. The contribution of yogurt and fromage frais and fruit to intrinsic and milk sugars decreased with age.

**Table 6.7, 6.7a and 6.7b**

### ***6.2.2 Contribution of food groups to intake of energy and sugars by Scottish Index of Multiple Deprivation***

The contribution of food groups to energy and sugars intake by SIMD quintile is shown in Table 6.8. There were highly significant overall and linear associations between the SIMD quintiles and the percentage contribution of several food groups to both energy and sugars.

Children in the more deprived quintiles derived a lower proportion of energy from pasta, rice and other cereals and a higher proportion from crisps and savoury snacks than children in the less deprived quintiles. Children in the more deprived quintiles also obtained a lower proportion of total sugars from fruit, and a higher proportion from confectionery and non-diet soft drinks.

There was a more marked pattern for the contribution of food groups to NMES intake, particularly for drinks. Children in the more deprived quintiles obtained a higher percentage of NMES from non-diet soft drinks (23% in the most deprived quintile vs. 14% in the least deprived quintile) and a lower percentage from fruit juice (3% in the most deprived quintile vs. 9% in the least deprived quintile).

Children in the more deprived quintiles derived a higher proportion of sucrose from non-diet soft drinks and a lower proportion from fruit, biscuits cakes and pastries and yogurt and fromage frais. The contribution of fruit to intrinsic and milk sugars was also lower in the children in the more deprived quintiles.

**Table 6.8**

### **6.2.3 Contribution of food groups to intake of energy and sugars by urban/rural classification**

Differences in the contribution of food groups to energy and sugars intake between urban and rural areas were generally less than those between deprivation categories. In urban areas the contribution of crisps and savoury snacks to total energy intake was higher, and the contribution of fruit juice to NMES intake was lower than in rural areas.

**Table 6.9**

## **6.3 Comparison of intake of energy and sugars with Dietary Reference Values and Scottish Dietary Targets**

### **6.3.1 Comparison of intake of energy and sugars with DRVs and Scottish Dietary Targets by age and sex**

Table 6.10 shows the Estimated Average Requirement (EAR) for energy in four age bands and the mean energy intake for the same age groups in this survey. The EAR defines the estimated average daily energy requirement of a given age group and sex at a given level of physical activity.<sup>1</sup> The mean energy intake expressed as a percentage of EAR for a given sex and age group in which all members were meeting their individual requirements would, therefore, be expected to be 100% of the EAR. Energy intake as a percentage of the EAR was calculated for each participant using the EAR appropriate for their age group and sex.

Energy intake as a percentage of the EAR was highest in younger children (109% in boys and 118% in girls aged 4-6 years) and lowest in the older children (78% in boys and 86% in girls aged 15-17 years).

Dietary Reference Values (DRVs) for NMES as recommended by the Committee on Medical Aspects of Food and Nutrition Policy (COMA) are expressed as population averages for percentages of energy intake derived from NMES.<sup>1</sup> The percentages are expressed in relation to energy from food and total dietary energy (including energy from alcohol). Current recommendations are shown in Table 6.10.

For NMES the recommended population average for adults is  $\leq 10\%$  of total energy or  $\leq 11\%$  food energy<sup>1</sup> (no value is given for children) and the Scottish Dietary Target for NMES for children is  $\leq 10\%$  of total energy. In the present survey the % food energy and % total energy are likely to be very similar since alcohol (which accounts for the difference between food energy and total energy) contributed less than 1% of energy intake in all children.

The NMES intake as a percentage of food energy was considerably higher than the recommended population average and the Scottish Dietary Target for children, with the values reaching 19.8% in boys and 18.7% in girls aged 15-17 years.

**Table 6.10**

### **6.3.2 Comparison of intake of energy and sugars with DRVs and Scottish Dietary Targets by Scottish Index of Multiple Deprivation and urban/rural classification.**

Energy intake and NMES expressed as a percentage of food energy were higher in children in the more deprived quintiles. As a result the mean energy intake as a percentage of the EAR and the mean NMES as a percentage of the population average was higher in these children.

The mean energy intake as a percentage of the EAR was highest in children in remote small towns and lowest in those in accessible rural areas. For NMES the percentage of the recommended value was highest in children in other urban areas and lowest in those in accessible small towns and remote rural areas.

## 7 INTAKE OF OTHER NUTRIENTS

This chapter describes the intake of total fat, saturated fatty acids, carbohydrate, protein, non-starch polysaccharides, iron and calcium for all children and by age, sex, deprivation and urban/rural classification. Intakes are also compared to Dietary Reference Values and Scottish Dietary Targets. The full list of the food groups and their contribution to total fat and saturated fatty acids intake are given in Appendix H.

### 7.1 Intake of other nutrients

The intake of other macronutrients, expressed as percentage of food energy and as grams per day (g/d), and of non-starch polysaccharides as g/d and iron and calcium as milligrams per day (mg/d) in all children and in sub-groups divided by age and sex is shown in Table 7.1. Statistical significance of differences between sexes and associations with age group shown in Tables 7.1a and 7.1b.

In all children the mean intake of total fat as a percentage of food energy was 32.9% with saturated fatty acids providing 13.8% of food energy. Carbohydrate and protein contributed 53.6% and 13.1% of food energy respectively.

#### 7.1.1 Intake of other nutrients by age and sex

There were no significant differences in the percentage food energy from total fat, saturated fatty acids, carbohydrate or protein between boys and girls, though the amounts of these nutrients as g/d was significantly higher in boys as a result of their higher energy intake (see Chapter 6). The intake of non-starch polysaccharides was not significantly different between boys and girls but the intake of iron and calcium was significantly higher in boys than girls. There were significant linear associations between age group and the contribution of saturated fatty acids, carbohydrate and protein to food energy with the contribution of saturated fatty acids and protein decreasing with age and the contribution of carbohydrate increasing with age. There was also a significant decrease in the intake of protein (g/d) and of calcium (mg/d) with increasing age.

Tables 7.1, 7.1a, 7.1b

#### 7.1.2 Intake of other nutrients by Scottish Index of Multiple Deprivation

Intake of other nutrients by quintile of SIMD is shown in Table 7.2. There were no significant associations between SIMD quintile and the contribution of total fat, saturated fatty acids or carbohydrate to food energy intake. There was a significant linear association between SIMD quintile and the contribution of protein to food energy intake with lower values in children in the more deprived quintiles. The higher energy intake in children in the more deprived quintiles (see Chapter 6) was reflected in the higher intakes of total fat, saturated fatty acids and carbohydrate (g/d) but no difference in protein intake (g/d) in children in the more deprived quintiles. There was no significant association between protein (g/d), non-starch polysaccharides (g/d), iron or calcium (mg/d) intake and SIMD quintile.

Table 7.2

#### 7.1.3 Intake of other nutrients by urban/rural classification

Intake of other nutrients by urban/rural area of residence is shown in Table 7.3. There were no significant associations between area of residence and the percentage of food energy from total fat, saturated fatty acids, carbohydrate or

protein or in the absolute intakes of total fat, saturated fatty acids, carbohydrate, non-starch polysaccharides (g/d) or of iron or calcium (mg/d). There was a significant association with the intake of protein (g/d) with the highest value in the children in the remote rural areas and lowest value in the children in the accessible rural areas.

**Table 7.3**

## **7.2 Contribution of food groups to intake of other nutrients**

Table 7.4 shows the food groups which contributed 5% or more to the intake of total fat, saturated fatty acids, carbohydrate, protein, non-starch polysaccharides, iron and calcium. The full list of the food groups and their contribution to total fat and saturated fatty acids intake are given in Appendix H.

The food groups contributing the highest proportion of total fat intake were biscuits, cakes and pastries (10%) and crisps and savoury snacks (9%). For saturated fatty acids the food groups providing the highest proportion were milk and cream (12%) and biscuits, cakes and pastries (10%). Bread excluding wholemeal and biscuits, cakes and pastries contributed 10% and 9% to total carbohydrate intake respectively. The main source of protein was milk and cream (14%) followed by meat and meat dishes (excluding processed meat) (10%). For non-starch polysaccharides the major food sources were fruit (16%) and bread excluding wholemeal (13%). Unsweetened breakfast cereals and bread excluding wholemeal contributed 13% and 11% of iron intake respectively, while calcium was derived principally from milk and cream (29%) with bread excluding wholemeal and yogurt and fromage frais each contributing 9%.

**Table 7.4**

### **7.2.1 Contribution of food groups to intake of other nutrients by age and sex**

There were significant differences in these values between boys and girls for many food groups but the magnitude of these differences was small (Table 7.4a). The differences in the values between age groups were more substantial, particularly for milk and cream (decreasing contribution to total fat, saturated fatty acids, protein and calcium with age); fruit (decreasing contribution to carbohydrate and non-starch polysaccharides with age group); confectionery (increasing contribution to saturated fatty acids with age group) and unsweetened breakfast cereals (decreasing contribution to iron intake with age group).

**Tables 7.4, 7.4a, 7.4b**

### **7.2.2 Contribution of food groups to intake of other nutrients by Scottish Index of Multiple Deprivation**

The contribution of food groups to the intake of total fat, saturated fatty acids, carbohydrate, protein, non-starch polysaccharides, iron and calcium by quintile of SIMD is shown in Table 7.5. There were significant overall associations and linear associations between SIMD quintile and the percentage contribution of several food groups to the intake of many other nutrients, particularly processed meats (higher contribution to total fat, saturated fatty acids and protein in the more deprived quintiles), crisps and savoury snacks (higher contribution to total fat, saturated fatty acids and carbohydrate in the more deprived quintiles); fruit (lower contribution to carbohydrate and non-starch polysaccharides intake in the more deprived quintiles); non-diet soft drinks (higher contribution to carbohydrate intake in the more deprived quintiles) and vegetables, excluding potatoes and baked beans (lower contribution to non-starch polysaccharides intake in the more deprived quintiles).

**Table 7.5**

### ***7.2.3 Contribution of food groups to intake of other nutrients by urban/rural classification***

There were significant associations between urban and rural areas and the contribution of food groups to the intake of many other nutrients. These were most marked for the contribution of processed meats to protein intake (8% in urban areas vs. 5% in remote rural areas) and the contribution of vegetables, excluding potatoes and baked beans, to non-starch polysaccharides intake (8% in smaller urban areas and accessible small towns vs. 12% in the remote rural areas).

**Table 7.6**

## **7.3 Comparison of intake of other nutrients with Dietary Reference Values and Scottish Dietary Targets**

### ***7.3.1 Comparison of intake of other nutrients with Dietary Reference Values and Scottish Dietary Targets by age and sex***

Table 7.7 Daily intake of other nutrients in relation to Dietary Reference Values and Scottish Dietary Targets in participants aged 4-17 years, by sex and age

shows the mean daily intake of fat, saturated fatty acids and carbohydrate as percentage of food energy. The mean daily intake of protein and non-starch polysaccharides (g/d), and the mean intake of iron and calcium (mg/d) are also presented and compared with the recommended levels in the four age bands used in the DRV report.

The mean intake of total fat as percentage of food energy was lower than the DRV population average and that recommended in the Scottish Dietary Targets (35% and  $\leq 35\%$  respectively) in all age and sex groups. However, the mean intake of saturated fatty acids was above the recommended levels in all age and sex groups.

The mean carbohydrate intake as percentage of food energy was a little above the recommended levels in all age and sex groups. The mean protein intake (g/d) was above the recommended level in all age and sex groups, particularly in the younger age groups. The mean intake of non-starch polysaccharides was below the recommended intake and close to the individual minimum for adults in all age and sex groups.

The mean iron intake (mg/d) was above the recommended level in younger children but below the recommended level in older children, particularly older girls, while the mean intake of calcium was above the recommended level for all age and sex groups, particularly the younger children.

**Table 7.7**

### ***7.3.2 Comparison of intake of other nutrients with Dietary Reference Values and Scottish Dietary Targets by Scottish Index of Multiple Deprivation and urban/rural classification.***

There were no clear patterns of adequacy of the intake of other nutrients between the SIMD quintiles (Table 7.8) or for urban/rural area of residence (Table 7.9).

## 8 OVERWEIGHT AND OBESITY

This chapter describes the prevalence of overweight and obesity in all children and in sub-groups of age, sex, deprivation category and urban/rural area of residence. The association between overweight and obesity and intake of energy and percentage energy as fat and sugars and of selected food groups high in fat or sugars is also presented.

### 8.1 Height and weight measurements

The mean height and weight of children with reliable measurements are shown in Table 8.1. As expected both height and weight increased linearly with age in both boys and girls. For each age group the mean height for boys was greater than that for girls but the differences were only significant for the oldest age group, 12-17 year olds. Boys in this age group were, on average, 6.5 cm taller than girls (166.2 vs. 159.7 cm).

The only significant difference in the mean weight between boys and girls was in those aged 12-17 years. In this age group boys were on average, 2.3 kg heavier than girls (57.6 vs. 55.3 kg).

**Table 8.1, Table 8.1a**

There was an association between mean height and SIMD quintile, with the highest mean value (145.3 cm) in the 2<sup>nd</sup> quintile and the lowest mean value (137.9 cm) in the most deprived (5<sup>th</sup>) quintile. The same pattern was seen in weight with a significant difference in the mean weight between the SIMD quintiles with the highest mean value (39.1 kg) in the 2<sup>nd</sup> quintile and the lowest mean value (34.7 kg) in the most deprived (5<sup>th</sup>) quintile, which probably reflects the strong association between height and weight. There was no significant difference in height or weight by area of residence.

**Table 8.2, Table 8.3**

### 8.2 Body Mass Index (BMI) and the prevalence of overweight and obesity

#### 8.2.1 BMI

BMI was calculated for the 1,615 participants who had reliable measurements of both height and weight. BMI was calculated by dividing weight in kilograms by height in metres squared. The UK 1990 centile charts<sup>1</sup> were then used to classify children as follows (results are presented in Section 8.2.2):

- underweight (defined as BMI below or equal to the 5<sup>th</sup> centile of the UK 1990 reference data)
- normal weight (defined as above 5<sup>th</sup> centile and below the 85<sup>th</sup> centile)
- overweight (defined as BMI equal to or above the 85<sup>th</sup> and below the 95<sup>th</sup> centile)
- obese (defined as BMI equal to or above the 95<sup>th</sup> centile)

In this chapter underweight and normal weight categories have been combined in the tables and are shown as *neither overweight nor obese*.

Z-scores (the number of standard deviations (SDs) above or below the median value) are also used to describe anthropometric data. If a measurement in an individual is the same as the median value for the reference population the z-score will be zero: values above the median will have positive z-scores with those more than 1 SD above the median having values above +1 and those more than 1 SD below the median having values below -1. The

overall mean z-score for BMI was +0.51 indicating that on average the values were 0.51 SD above the median values in the reference population.

There was a strong linear association between mean BMI and age group increasing from 16.2 kg/m<sup>2</sup> for boys aged 3-7 to 20.5 kg/m<sup>2</sup> for boys aged 12-17. In girls the corresponding increase was 16.4 to 21.3 kg/m<sup>2</sup>. Mean BMI was higher in girls than boys overall (18.4 vs. 18.0 kg/m<sup>2</sup>) and in all age sub-groups but the difference was only significant for the 12-17 year old age group. The BMI z-score was not significantly different between the three age groups or between boys and girls.

**Table 8.4, 8.4a, 8.4b**

There was a significant overall association between BMI and SIMD quintiles but no evidence of a linear association: children in the least deprived (1<sup>st</sup>) quintile had the lowest mean BMI (17.9 kg/m<sup>2</sup>) while those in 2<sup>nd</sup> quintile had the highest (18.6 kg/m<sup>2</sup>). There were significant associations between both BMI and BMI z-score and the urban/rural areas of residence, with lowest values in the accessible small towns and accessible rural areas.

**Table 8.5, Table 8.6**

### **8.2.2 Prevalence of overweight and obesity**

Overall the prevalence of overweight and obesity was 14% and 17% respectively. There were no significant differences between the sexes in the prevalence of overweight and obesity overall: 13% of boys and 15% of girls were overweight and 16% of boys and 18% of girls were obese. However, significantly fewer boys in the youngest age group were obese compared with girls (8% vs. 18%). The prevalence of obesity was significantly higher amongst 12-17 year old boys than the 3-7 year old boys (21% vs. 8%). About a third of children were either overweight or obese: 30% of boys and 33% of girls.

**Table 8.7, 8.7a, 8.7b**

The overall prevalence of overweight and obesity was similar to that reported in the 2003 Scottish Health Survey (SHS).<sup>2</sup> In the SHS, which surveyed children aged 2-15, 16.7% of boys and 16.1% of girls were classed as overweight and 18.0% of boys and 13.8% of girls were classed as obese using the same classification method as used in this survey.

In addition to the UK reference standards for BMI, new international cut-offs have been proposed<sup>3</sup> and have been used in many countries though the issues determining the choice of national vs. international reference data are complex.<sup>4</sup> For comparison with other countries the prevalence of overweight and obesity was also assessed using the International Obesity Task Force cut-offs which are set at centile values close to the 89th and 99th centile of the international reference population data. Using these standards the prevalence of overweight in the present survey was 18% and the prevalence of obesity was 7%.

The prevalence of underweight amongst children was low at 2%, (not shown in tables) compared to an expected value of 5% for the 5<sup>th</sup> percentile.

### **Prevalence of overweight and obesity by SIMD and urban/rural classification**

There was an association between prevalence of *overweight including obese* and deprivation. In both sexes, the highest proportion of children in the *overweight including obese* category appeared in the middle (3<sup>rd</sup>) quintile of deprivation (33% for boys and 38% for girls) while the lowest proportion of children in the combined *overweight including obese* category was in the least deprived (1<sup>st</sup>) quintile (25% for both sexes).

**Table 8.8**

No association was found between the prevalence of overweight and obesity and urban/rural classification.

**Table 8.9**

### 8.3 Intake of selected food groups and overweight and obesity

In this section intake of selected foods by **all** consumers is examined in relation to overweight and obesity. Food groups were selected based on their content of fat or sugar or both.

There was little evidence for associations between the intake of foods high in fat or sugar and overweight and obesity. The only significant linear association between BMI group and intake of foods was for the food group biscuits, cakes and pastries with the lowest intake in the obese group but the difference in the amount consumed between the groups was small. The results of these analyses could be influenced by dieting and/or under-reporting in the overweight and obese. As no information was collected on dieting behaviour and no adjustment of the data has been made for possible under-reporting the differences between the BMI categories should be interpreted with caution.

**Table 8.10**

### 8.4 Association between intake of energy, fat and sugars and overweight and obesity

There was no statistical evidence for an association between energy intake (MJ/day) and BMI group although energy intake in the overweight group tended to be higher than that in the *neither overweight nor obese* group and the obese group. There were small but significant linear associations between BMI group and the percentage of food energy from total fat, saturated fatty acids and total sugars. Intake of total fat and saturated fatty acids as a percentage of energy was lower in overweight and obese children than in children who were neither overweight nor obese. In contrast, total sugar intake was higher in overweight and obese children than in those who were neither overweight nor obese.

**Table 8.11**

## 9 PHYSICAL ACTIVITY

### 9.1 Introduction

Physical activity is a broad term to describe movement of the body that uses energy. There are many types of physical activity including exercise, sport, play, dance and active living such as walking, housework and gardening. Physical activity does not have to be strenuous to have significant effects on people's health, general well being and productivity.<sup>1</sup>

Regular physical activity is considered vital for healthy growth. The benefits of being active from an early age include:

- Reducing the risk factors for heart and circulatory diseases
- Helping in preventing weight gain
- Promoting positive mental health

The Scottish Executive's physical activity targets are outlined in the Physical Activity Task Force 2003 publication *Let's make Scotland more active: A strategy for physical activity*.<sup>1</sup> Its primary recommendation is that all children and young people, including children with disabilities, should take part in at least one hour of moderate physical activity a day.

The long-term target is for 80% of all children aged 16 and under to meet the minimum recommended level of physical activity by 2022 i.e. one hour of moderate physical activity each day.

This chapter presents data on participation in physical activities, overall physical activity levels and a measure of inactivity. The association between physical activity and obesity is examined. The questions used in this element of the survey were the same as those used in the 1998 and 2003 Scottish Health Surveys (SHS)<sup>2,3</sup> and included questions on activities that were thought to account for the largest part of children's total activity. The physical activity questions did not include any activity undertaken as part of the school curriculum.

Although this survey used the same questions as those used in the 1998 and 2003 SHS there were differences in other areas of the methodology employed such as the sampling and age range. In addition, the field work for this study was undertaken between May and September in contrast to the SHS which was a continuous survey with field work being conducted throughout the year. Levels of physical activity are likely to be higher in the summer months and in particular in the school holidays. The results of the two surveys are therefore not directly comparable.

### 9.2 Physical activity questions

Information was sought on the four different types of physical activity thought to account for the largest part of children's total activity: sport/exercise, active play, walking and housework/gardening. All children were asked questions on the number of days and the time spent each day in the last 7 days on each of these physical activities. Children of all ages

were asked about each of these activities in contrast to the SHS in which children under 8 years were not asked about their participation in housework/gardening.

Information about sports and exercise and active play was collected separately for weekend and weekdays. Questions on walking and housework/gardening did not distinguish between these activities carried out on a weekday and at weekends.

There was no lower time limit for the inclusion of sport/exercise or active play but only episodes of housework/gardening which lasted for at least 15 minutes were included. The questions about walking asked about walks of at least 5 minutes duration.

No information on the intensity of housework, sports and exercise or active play was collected. For the purpose of this report it is assumed that all activity was at least of moderate intensity.

Questions were also asked about the time spent in front of a screen as a measure of physical inactivity. Children were asked about the average number of hours spent sitting in front of a television or computer screen on an average week day and on an average weekend day.

Further details of the information sought in relation to physical activity can be found in the 2003 SHS.<sup>3</sup>

### **9.2.1 Participation in physical activities over the previous week**

This section presents reported participation in physical activity by number of days and hours participation in the previous week. It should be noted that the sample in this survey is not the same as in the 2003 SHS<sup>3</sup> which included children aged 2-15 years compared to 3-16 years in this survey.

Table 9.1 shows the number of days on which children participated in all physical activities in the previous 7 days. This adds together the number of days on which sport and exercise, active play, housework/gardening and walking were done. This summary of overall participation is equivalent to the number of occasions children engaged in physical activities, as it assumes that each activity was done on a different day. So for example, if a child had participated in sports and exercise and active play on the same day, this would get counted as two days of activity. For this reason the number of days of participation exceeds the number of days in the week. For example, a child who had participated in sports and exercise on five days and undertook a walk of a least 5 minutes duration on five days would be counted as having participated on 10 days when calculating overall participation in physical activities. This is the same method as used in the 2003 Scottish Health Survey.

It should be noted that calculations of the mean number of days are based on all children, including those that reported that they did not participate in any activity.

Virtually all children had participated in some form of physical activity in the previous week and most children (97%) participated in physical activities on 5 days or more in the previous week. This was the case for both boys and girls (97% for both).

There was a linear association between age group and participation in physical activities in the previous week. The number of days spent participating in physical activities in the previous week was lower in the oldest age group than in the two younger age groups. The association was significant in both girls and boys.

The mean number of days participation was significantly lower for girls than for boys overall, and in the eldest age group.

**Table 9.1, 9.1a and 9.1b**

The amount of time spent on physical activities is presented in Table 9.2. Calculations of mean time spent on each activity type are based on all children, including those who did not participate in any activities. Children had spent an average of 19.7 hours engaged in physical activities in the previous week. Boys had spent significantly more time than girls on physical activities (21.2 hours vs. 18.0 hours).

Time spent participating in physical activities was associated with age group. There was little difference between the two youngest age groups in the number of hours spent participating in physical activities for both boys and girls. However there was a decrease in the number of hours spent participating in these activities for the oldest age group (12-17 years). This was significant in girls but not in boys. Girls aged 12-17 spent an average of 15.1 hours participating in physical activities compared to 19.9 hours for boys.

**Table 9.2, 9.2a and 9.2b**

### **9.2.2 Summary physical activity levels over the previous week**

The frequency and time spent on physical activity and the intensity of that activity are all important factors in measuring levels of physical activity.

Following a review and consultation exercise by the Health Education Authority in 1997, a set of recommendations on physical activity levels for young people aged 5-18 were set.<sup>4</sup> These recommendations were endorsed by the then Scottish Executive.<sup>1</sup> The primary recommendations were:

- All young people should participate in physical activity of at least moderate intensity for one hour per day.
- Young people who currently do little activity should participate in physical activity of at least moderate intensity for at least half an hour per day.

In this section participation in the different types of activity has been summarised into a frequency-duration scale, by taking account of the average time spent participating in physical activities and the number of active days in the previous week. There were no questions on level of intensity of the physical activities so it is assumed that participation in activity was at least of moderate intensity.

The summary physical activity levels are as follows:

- High: active for 60 minutes on 7 days in the last week. Assuming that all reported activities were of at least moderate intensity, this group refers to those children who met the recommended levels of physical activity.

- Medium: active for 30-59 minutes on 7 days in the last week. This group represents those achieving the lower recommended level which is at least 30 minutes (but less than an hour) of at least moderate intensity per day. Again activities were assumed to be undertaken at moderate intensity levels.
- Low: active at a lower level or not active at all. This group refers to children who did not meet either of the recommended physical activity levels.

Overall, 86% of children reached the higher recommended physical activity level. A significantly higher proportion of boys reached this level - 89% of boys compared with 83% of girls. The difference between the sexes in the proportions of children reaching the higher recommended activity level was significant only in the 12-17 age group (86% for boys, 69% for girls). A further 5% of boys and 9% of girls reached the medium level of activity. The 2003 SHS<sup>3</sup> and many other studies have also found that boys are more physically active than girls.

The proportion of children reaching the higher recommended physical activity level was greater than the proportion reaching this level in the 2003 SHS<sup>3</sup>. In the 2003 SHS 74% of boys and 63% of girls reached the higher recommended physical activity level. As stated previously it is likely that this is due in part to the timing of fieldwork.

There was a significant association between age group and activity levels for all children and for girls. Amongst both boys and girls the levels of both high and medium activity were very similar in the two youngest age groups. In both sexes, levels of activity decreased in the oldest age group although there was a sharper decline in activity amongst girls (boys 93%, girls 85%).

This pattern of decrease in activity with increasing age and the sharper decline amongst girls than boys is consistent with that found in the 2003 SHS<sup>3</sup> and in other studies.

**Table 9.3, 9.3a and 9.3b**

### **9.2.3 Time spent sitting at a screen**

Boys spent more time sitting in front of a screen than girls (2.2 vs. 2.0 hours per day). The difference in time between boys and girls was significant overall and for the 3-7 and 12-17 year age group.

There was a significant overall association and a linear trend between the time spent in front of a screen and age group. This association was significant for both sexes with 14% of both boys and girls in the oldest age group (12-17 years) sitting in front of a screen for an average of at least 4 hours a day compared to 5% of boys and 4% of girls in the youngest age group (3-7 years).

**Table 9.4, 9.4a and 9.4b**

### **9.2.4 Physical activity by Scottish Index of Multiple Deprivation**

Table 9.5 presents the proportion of children meeting the higher physical activity recommendation by SIMD quintile. There was no clear pattern in the relationship between those meeting the physical activity recommendations and level of deprivation for either sex.

Children in all quintiles of deprivation met the target of 80% achieving the higher physical activity recommendation with the exception of girls in the 2nd quintile, where 79% achieved the physical activity recommendation.

**Table 9.5**

### **9.2.5 Physical activity by urban/rural classification**

There was no clear relationship between the proportion of children reaching the current physical activity recommendations and urban/rural classification.

**Table 9.6**

## **9.3 Physical activity and Body Mass Index (BMI)**

In this section, levels of activity (the proportion of children meeting the recommended physical activity level) by BMI is examined. Children are classified into one of two BMI groups for the analysis in this section: *neither overweight nor obese* or *overweight including obese*.

There were significant differences in the proportion of children reaching the physical activity recommendations by BMI classification. A higher proportion of children in the *neither overweight nor obese* category reached the recommended level compared with those in the *overweight including obese* category (88% vs. 81%). The differences were significant for the two younger age groups but were not significant for the oldest age group (12-17 year olds).

The target of 80% of children reaching the higher physical activity recommendation was achieved by boys in both BMI categories and in all age groups. In contrast, only girls in the two youngest age groups met the target in both BMI categories. Girls in the oldest age group and in both BMI categories failed to meet the target.

**Table 9.7**

### **9.3.1 Body Mass Index, physical activity, Scottish Index of Multiple Deprivation and urban/rural classification**

#### **Scottish Index of Multiple Deprivation (SIMD)**

Table 9.8 shows there was no clear pattern in the association between BMI category and the proportion meeting physical activity recommendations by SIMD. A smaller proportion of children in the *overweight including obese* category met the physical activity recommendations than those in the *neither overweight nor obese* category with the exception of those in the 2<sup>nd</sup> quintile. These differences were only significant in the 3<sup>rd</sup> and 5<sup>th</sup> quintiles.

The only group not meeting the target of 80% reaching the higher physical activity recommendation was the *overweight including obese* group in the most deprived (5<sup>th</sup>) quintile.

**Table 9.8**

### **Urban/rural classification**

Bases for *overweight including obese* categories fell below 50 in three urban/rural categories so statistical tests were not carried out on these groups.

There were no clear patterns in the proportions meeting the physical activity recommendations by BMI and urban/rural classification.

There were significant differences between the BMI categories in the proportions meeting the physical activity recommendations in children living in the large urban and accessible rural areas. Children classified as *overweight including obese* in these two areas of residence were also the only groups not to achieve the 80% target.

**Table 9.9**

### **9.3.2 Time spent participating in physical activities in the last week by Body Mass Index**

Overall there was a significant association between the time spent participating in physical activities in the last week and BMI category. A higher proportion of children in the *neither overweight nor obese* category spent 14 hours or more a week participating in physical activities than those in the *overweight including obese* category (64% vs. 58%). This significant association was also seen in the 3-7 and 12-17 year age groups.

**Table 9.10**

### **9.3.3 Time spent at a screen by Body Mass Index**

For all children and for boys there was a significant association between BMI category and time spent sitting in front of a screen. A higher proportion of children in the *overweight including obese* category spent more than 3 hours in front of a screen than those in the *neither overweight nor obese* category (25% vs. 20%). For boys the proportions were 28% vs. 21%.

**Table 9.11**

## 10 DENTAL HEALTH

### 10.1 Introduction

Scottish children have worse dental health than those in the UK as a whole,<sup>1</sup> and within Scotland, dental health has changed little between 1998 and 2003.<sup>2</sup> The development of dental caries (decay) is influenced by previous disease, social factors, use of fluoride, plaque control, saliva, medical history and diet.<sup>3</sup> The dietary factors include the amount of sugar consumed, sugar concentration of food, physical form of carbohydrate, oral retentiveness (length of time teeth are exposed to reduced plaque pH), frequency of eating meals and snacks, length of interval between eating, and sequence of food consumption.<sup>3</sup> In particular, it is the amount and frequency of consumption of NMES that are the major causes of dental caries in the UK.<sup>4</sup>

The questions used in this survey were the same as those used in the 2003 Scottish Health Survey.<sup>2</sup> The chapter reports on the dental health of children and provides information on attendance at the dentist and the type of dental treatment received including treatment for decay (fillings or teeth taken out due to decay). Information is not included on the level of decay, such as the number of fillings or the number of teeth removed due to decay. The data is presented by age and sex and then by SIMD and urban/rural classification. The association between dental disease and intake of total sugar, NMES and foods with high sugar content is explored.

### 10.2 Attendance at a dentist

The vast majority of children (97%) had attended the dentist. There was a marked association between the proportion of those who had ever attended the dentist and increasing age. At age 3-7, 94% of children (95% of boys and 92% of girls) had attended the dentist. This proportion rose to 99% (98% boys and 100% girls) by age 12-17.

The average age of first attendance at the dentist for all children was 2.2 years for both boys and girls.

The most common reason for first attendance amongst both sexes was to get used to going to the dentist (boys 59%, girls 61%). Going for a check up was the second most common reason. The only significant difference between the sexes was in the 8-11 year old age group. In this group boys were more likely than girls (32% vs. 21%) to attend the dentist for the first time for a check up and less likely than girls to go to get used to going to the dentist (59% vs. 68%).

**Table 10.1, 10.1a, 10.1b**

### 10.3 Dental treatment

There were no significant differences between the sexes in the type of dental treatment received. About a third of children had received treatments to stop decay such as painting and sealing. A similar proportion had had fillings but no teeth taken out due to decay (boys

32%, girls 31%). In addition, another 17% of boys and 16% of girls had had both fillings and teeth extracted due to decay.

All types of treatment were more common in older children with the exception of teeth extraction but no fillings. Those aged 8-11 years were more likely to have teeth extracted but have no fillings.

Over half of all children had received treatment for decay. The likelihood of receiving treatment for this reason increased with age. A quarter of children in the youngest age group, 3-7 years, had received treatment for decay (boys 26%, girls 26%). This proportion rose to almost three quarters for those aged 12-17 years (boys 74%, girls 73%).

**Table 10.2 10.2a, 10.2b**

## **10.4 Dental health by socio-demographic characteristics**

### **10.4.1 Scottish Index of Multiple Deprivation (SIMD)**

There was no clear trend in the proportion of children who had never attended a dentist across the SIMD quintiles. However there were clear trends in some of the type of treatments received by level of deprivation. The likelihood of having teeth taken out but no fillings and having both fillings and teeth taken out increased with increasing deprivation. Amongst boys, those living in most deprived areas were seven times as likely to have had teeth removed than those in the least deprived areas. Girls in the most deprived (5<sup>th</sup>) quintile were three times as likely to have had teeth removed as girls in the least deprived (1<sup>st</sup>) quintile.

All treatment for decay was also associated with increasing deprivation in both sexes. Boys in the most deprived quintile were twice as likely to have had treatment for decay than boys in the least deprived quintile (71% vs. 35% respectively). This trend was also apparent in girls although the difference between the highest and lowest quintiles was not as great (65% vs. 43%). These trends are likely to reflect higher rates of decay in more deprived groups.

**Table 10.3**

### **10.4.2 Urban/rural classification**

Statistical tests were not carried out for dental treatment by urban/rural classification for boys and girls separately due to small numbers of children and results should be interpreted with caution.

Boys living in other urban areas, remote small towns and remote rural areas were most likely never to have attended a dentist (4% and 5% and 16% respectively). This compared to 1 or 2% never attending the dentist in other areas. There was a similar pattern amongst girls, for those living in other urban areas and remote small towns where 6% and 7% had not attended a dentist. However all girls in remote rural areas had attended a dentist.

Around a half of all children in all types of area had received dental treatment for decay with the exception of boys in other urban areas and boys and girls in remote small towns where the percentage of those receiving treatment for decay rose to 60% or more.

**Table 10.4**

## **10.5 Association between diet and dental health**

Intakes of total sugars, NMES and selected food groups were compared between children who had received treatment for decay (had either fillings or teeth taken out due to decay) and children who had never received treatment for decay. The food groups selected were those that contributed at least 5% to the intake of total sugars and NMES, and also crisps and savoury snacks which may be important in the development of dental caries.

Statistical tests were not carried out for girls aged 3-7 years due to low numbers of children in the group treated for decay. It should also be noted that untreated caries may be more common in the youngest (3-7 years) age group, therefore for this age group, the comparison of diet between those who had had treatment for decay and those who had not may not be a true reflection of dietary intake of those with and without dental caries.

### ***10.5.1 Intake of total sugars and NMES and treatment for decay***

The mean intake of total sugars, expressed as a percentage of food energy, was not significantly different between children who had been treated for decay (29.1% food energy) and those who had never been treated for decay (28.8% food energy). However, mean NMES intake was significantly higher in children who had been treated for decay (18.5% food energy) than in children who had not (16.1% food energy). This difference in NMES intake was significant in boys and in girls, and was most evident in children aged 12-17.

**Table 10.5**

### ***10.5.2 Intake of selected foods and treatment for decay***

Children who had been treated for decay reported significantly higher intakes of crisps and savoury snacks, confectionery, and non-diet soft drinks than those who had never been treated for decay. Boys who had been treated for decay also reported higher intakes of biscuits, cakes and pastries. In boys, these significant differences were seen for crisps and savoury snacks and confectionery in all age groups, and for non-diet soft drinks in 12-17 year olds. In girls these significant differences were only seen in 12-17 year olds.

Children who had received treatment for decay also reported significantly lower intakes of milk and cream, yogurt and fromage frais, fruit and fruit juice including smoothies than those who had never received treatment for decay. These significant differences were only seen for fruit and fruit juice including smoothies in 8-11 and 12-17 year olds.

## **11 DISCUSSION AND RECOMMENDATIONS**

This chapter reviews the design and results of the study and their implications for future research and for health improvement in Scottish children.

### **11.1 Survey methodology**

#### ***11.1.1 Survey population***

The Child Benefit records used as the sampling frame for this survey provided a valuable opportunity to approach a nationally representative sample of children in Scotland. The final sample size was close to the intended target figure of 1,600 children, which was chosen to allow robust estimates of variables for sub-groups defined by age, sex and socio-economic deprivation. However, due to the small proportion of the population in remote and rural areas the ability of the survey to detect differences between children living in these areas compared to those in urban areas was limited.

The overall response of 66% achieved in this survey suggests that the method used to contact the children and parents was acceptable to the majority of those approached. There was no evidence of response bias by socio-economic deprivation (as defined by quintile of the Scottish Index of Multiple Deprivation or SIMD) for the interview but for the FFQ there was some evidence of response bias by socio-economic deprivation, with lower response from children in areas of greater deprivation. In spite of this a total of 295 children in the most deprived quintile of SIMD completed an FFQ, allowing confidence to be placed in weighted estimates of food and nutrient intake for this group.

#### ***11.1.2 Dietary assessment methods***

This survey was the first national survey in the UK to use FFQs as the primary dietary assessment method. The agreement between the FFQ and the diet diary and 24-hour recall in the sub-samples suggest that the values of NMES, total fat and saturated fatty acids as % energy provided by the FFQ could be used for comparison with targets and with data collected using other methods for these nutrients.

The FFQ was chosen as it required much less staff time for coding the foods and drinks and estimating the weight of each item than the diet diary or 24-hour recall.

During the interview the instruction for the completion of the diet diaries took around 5 minutes while the median time taken for collection of a single 24-hour recall was 25 minutes. The diet diaries then required 1 hour or more of experienced nutritionists' time to code and enter the data per day of data collected while the 24-hour recall required around 1.5 hours for coding and entry due to the greater use of recipes and the collection of more qualitative information. By contrast each FFQ could be entered by data entry clerks in under 15 minutes with less than a third of the FFQs needing further time (on average 5 minutes) for a trained nutritionist to code additional foods listed by the respondents. Checking of the completed FFQs prior to the face to face home interview by the trained field workers reduced the problem of missing data and ensured that the quality of the data collected was high.

For energy and other nutrients there was evidence of over-estimation by the FFQ which varied between the nutrients. There was some evidence for greater over-estimation in the younger children, in whom the FFQs were usually completed by the parent, which limited comparisons of energy and other nutrients by age sub-groups. The sub-groups used in the validation studies were not large enough to assess whether the validity of the FFQs differed by socio-economic deprivation level. For this reason the comparisons of the FFQ derived food and nutrient intake between the deprivation categories should be seen as an indication of broad patterns rather than precise estimates of the differences.

There was little evidence of response bias by socio-economic deprivation for the 24-hour recall but the response to the diet diary was much lower in children in the more deprived areas. This suggests that surveys using diet diaries need to ensure that sample size is sufficient to provide a reasonable number of subjects in more deprived areas and to use weighting methods to derive estimates of population intakes where the sample size in the sub-groups is not in proportion with the size of the sub-groups in the total population.

### **11.1.3 Anthropometric measurements**

The measurement of height and weight by field workers in the home was acceptable to the majority of the children, with only 4% refusing the measurements. The BMI obtained was compared with UK reference data<sup>1</sup> rather than international reference data<sup>2</sup> which uses cut-off points closer to the UK 89<sup>th</sup> and 99<sup>th</sup> centiles for overweight and obesity respectively and hence provides lower estimates of the prevalence, particularly for obesity, than those based on the UK data.

### **11.1.4 Physical activity**

Although the same questions were used to assess the proportion of children who met the recommended physical activity levels in the present survey as in the 2003 Scottish Health Survey, the proportion of children meeting the recommendations was considerably higher in the present survey (86% of the children in the present survey compared with 74% of boys and 63% of girls aged 2-15 years in the 2003 Scottish Health Survey<sup>3</sup> (SHS)). A possible explanation is that in the present survey data was collected in the summer months (May – September) when children are likely to be more active, whereas in the SHS data was collected continuously over a 19-month period. This suggests that future surveys of activity in children in Scotland may need to take seasonal variation in activity into account.

Due to the high proportion of children meeting the recommended level of activity in the present survey, sub-group analyses of this variable were limited by the low numbers of children in each sub-group who did not meet the recommendation.

### **11.1.5 Dental health**

The questions on dental health used in the present survey were also the same as those used in the 2003 SHS. These questions relied on the accuracy of recall by the parents or children of dental treatment received and may therefore differ from figures based on dental records. The questions do not therefore provide reliable estimates of the proportion of children who had caries as the questions only asked about treatment for caries: mild forms of caries or caries in children who had not visited a

dentist were not included so the true prevalence of caries will have been higher than the figures reported here. There was also no assessment of the severity of caries in those who had had treatment.

### Key points

- Child Benefit Records provided a very effective sampling frame for the survey.
- 66% of respondents completed the FFQ and face to face interview
- There was some evidence of lower response to the FFQ in areas of greater socio-economic deprivation.
- Although the sample was representative of urban, rural and remote sub-groups of the Scottish population, comparisons between these sub-groups were limited by the low numbers of children in rural and remote areas.
- The FFQ provided similar estimates of NMES, total fat and saturated fatty acids (as % energy) to the diet diary and 24-hour recall, but required much less trained staff time.
- For energy and many other nutrients the FFQ overestimated the intake by varying amounts.
- Levels of physical activity recorded may have been influenced by the fact that the survey was carried out in summer months only.
- Estimates of dental caries relied on parent- or child-reported treatment for caries and therefore did not include mild or untreated caries.

### Recommendations

Use of the Child Benefit records as the sampling frame should be considered in any future study monitoring children's diets.

The FFQ as used in this study proved to be a cost effective and robust method for measuring intake of NMES and fat and saturated fatty acid as percentage food energy. It is recommended that this method be considered in monitoring the intake of these nutrients.

## 11.2 Survey results

### 11.2.1 Intake of foods and nutrients

The FFQ provided evidence that the majority of children consumed a wide range of foods: of the 32 food groups, foods from each group were consumed once a month or more by at least two thirds of the participants apart from wholemeal bread, white fish, shell fish and dishes, nuts and seeds and powdered beverages.

There were clear relationships for many of the food groups between the amount of food consumed among consumers and SIMD, with more pasta, rice, vegetables, fruit and fruit juice consumed by children in less deprived areas and more eggs, processed meats, chips, crisps, confectionery and soft drinks consumed by children in more deprived areas. In spite of these differences the trends in energy, NMES,

total fat and saturated fatty acids were not marked. This unexpected finding may be the result of the fact that some food groups which were major contributors to energy and fat intake such as biscuits, cakes and pastries and milk and cream were consumed in similar amounts in all SIMD quintiles. However, for NMES the greater fruit juice consumption in the children in less deprived areas compensated for the lower non-diet soft drink intake. It is also important to highlight the fact that the present survey was not designed to provide accurate estimates of vitamin and mineral intake which are likely to differ more widely with deprivation level as a result of the differences in food groups consumed.

There was clear evidence that the intake of NMES was considerably higher than the Scottish Dietary Target of  $\leq 10\%$  in all children and in all sub-groups. The average intake of total sugar was 138g per day, of which 64g per day (approximately 13 teaspoons) was sucrose. The overall mean intake of NMES if of 17.4% of food energy was similar to the values of 16.7% in boys and 16.4% in girls in the NDNS survey of UK children aged 4-18<sup>4</sup> carried out in 1997 and to the value of 17.1% in boys and 16.5% in girls aged 2-18 in the Low Income Diet and Nutrition Survey<sup>5</sup> (LIDNS) carried out in 2004, suggesting that this is a UK-wide problem. The high intake of NMES in Scottish children is consistent with the findings of the Health and Behaviour in School-age Children (HBSC) survey<sup>6</sup> which found that Scotland ranked second highest of 35 countries for consumption of sweet drinks and third highest for frequent consumption of sweets.

The main sources of NMES in the present survey were non-diet soft drinks, biscuits, cakes and pastries and confectionery, which is consistent with the patterns seen in both the NDNS and LIDNS. Soft drinks and confectionery are inexpensive, highly palatable and widely available and are therefore likely to be consumed between meals, thereby adding to the risk of dental disease. However it is also worth pointing out that in the present survey 13% of NMES was derived from fruit juice including smoothies (6%) and yogurt and fromage frais (7%), which may be considered to be healthier alternatives to biscuits and confectionery. The fact that fruit juice and smoothies may be less beneficial for dental and metabolic health than whole fruit may need to be highlighted in future health messages.

The average intake of total fat of 32.9% food energy in the present survey was below the DRV population average of 35% and the Scottish Dietary Target of  $\leq 35\%$ . The value was also a little lower than the values of 35.4% in boys and 35.9% in girls reported in the NDNS and lower than the values of 36.1% in boys and 35.7% in girls aged 2-18 reported in the LIDNS. The average saturated fatty acid intake of 13.8% food energy was higher than the DRV population average of 11 % food energy and the Scottish Dietary Target of  $\leq 11\%$  food energy but similar to the values of 14.2% in boys and 14.3% of girls in the NDNS and 14.2% in boys and 14.0% in girls aged 2-18 in the LIDNS. The leading sources of saturated fatty acids were milk and cream and biscuits, cakes and pastries, which suggests that these foods need to be targeted in healthy eating messages to reduce saturated fatty acid intake in children.

### **11.2.2 Overweight and obesity**

The prevalence of overweight and obesity in the present survey of 14% and 17% respectively was higher than the expected distribution based on the centile cut-offs used (10% lying between  $\geq 85^{\text{th}}$  and  $< 95^{\text{th}}$  centile and 5%  $95^{\text{th}}$  centile). The values were very similar to the figures of 16% for overweight and 16% for obesity in children aged 2-15 years in the 2003 SHS. As in the SHS there was no clear evidence of a linear association with deprivation. There was also little evidence for differences in

the intake of foods or nutrients between the children who were *neither overweight nor obese* and the overweight or obese children. However this type of cross-sectional analysis may well have been affected by differential reporting bias, with the overweight and obese children under-reporting high sugar, high fat foods, or by dietary restraint in the overweight and obese groups.

### **11.2.3 Physical activity**

The results of the present survey provide some support for an association between physical activity and overweight and obesity. The proportion of *overweight including obese* children who met the physical activity recommendations of at least 60 minutes on all 7 days was lower in these children than in the non-overweight children while the proportion spending two or more hours sitting at a screen on an average day was significantly higher in the *overweight including obese* children than in the neither overweight nor obese children. However, these cross-sectional associations cannot provide evidence of a causal link between physical activity and overweight, since overweight and obese children may be less active as a result of their greater weight.

### **11.2.4 Dental health**

The fact that there was no association between total sugars intake and treatment for decay but there was a clear association with NMES intake suggests that this component of foods contributes to the risk of dental decay and also suggests that the FSA's current sugars classification is useful in identifying the components of the diet which adversely affect dental health. Children who had had treatment for decay consumed almost twice the amount of non-diet soft drinks and 50% more confectionery than children who had not had treatment for decay, but also consumed less fruit juice and yogurt which also contribute to NMES.

There were clear differences in the proportion of children who had had treatment for dental decay by socio-economic status, ranging from 39% in the least deprived quintile to 68% in the most deprived quintile. The fact that the intake of foods differed by socio-economic status while there was little difference in the intake of NMES suggests that the type, timing and frequency of consumption of foods may also be important in determining risk of dental disease.

## Key points

- The intake of NMES as % food energy was 17.4%, considerably higher than the Scottish Dietary Target of  $\leq 10\%$  total energy but similar to values from other surveys of UK children.
- The intake of total fat as % food energy was 32.9%, which met the Scottish Dietary Target of  $\leq 35\%$  and was a little lower than values from other surveys of UK children.
- The intake of saturated fatty acids as % food energy was 13.8%, which was higher than the Scottish Dietary Target of  $\leq 11\%$  but similar to values from other surveys of UK children.
- Despite clear associations between the consumption of many foods and drinks and socio-economic deprivation, differences in energy intake and NMES, total fat and saturated fatty acids as % energy between the socio-economic sub-groups were small.
- Overall 15% of children were overweight and 17% were obese, which is consistent with other data from Scottish children.
- There was no evidence for associations between food or nutrient intake and overweight or obesity, but this could have been due to dietary restraint or under-reporting by overweight and obese children.
- There was some evidence for an association between physical activity and overweight and obesity in the expected direction.
- There was clear evidence for an association between NMES intake and dental caries, though this was not seen for total sugars.

## Recommendation

Measures need to be taken to reduce the high intake of the main sources of NMES identified in this survey, namely non-diet soft drinks, biscuits, cakes and pastries and confectionery. Such measures should be directed at all children.

## 11.3 Implications

### 11.3.1 Implications for further research

This survey provides a robust baseline for future studies of NMES and fat intake in Scottish children, which could be used for monitoring the impact of policy initiatives aimed at improving children's diet, such as Hungry for Success<sup>7</sup> and the Schools (Health Promotion and Nutrition) (Scotland) Act 2007.<sup>8</sup>

The results could also provide baseline data for longitudinal studies of diet and health in the participants in the present survey which could provide more useful information on the relationship between diet and the development of overweight and obesity. To resolve the question of whether the energy intake of overweight and obese children is under-reported to a greater extent than *neither overweight nor obese* children would require objective estimates of energy intake e.g. using doubly labelled water to measure habitual energy expenditure.

The possibility of an association between physical activity (or inactivity) and intake of energy, NMES, total fat and saturated fatty acids could be explored. However, more detailed information on the type, intensity and duration of activities would be beneficial.

Longitudinal studies of the present survey population could also investigate whether low physical activity precedes or succeeds weight gain.

### **11.3.2 Secondary analysis**

The survey has provided the opportunity for further secondary analysis of the data. This will include:

- Analysis of dietary patterns (using principal component analysis) and exploration of their possible relationships with age, sex, socio-economic deprivation and overweight and obesity
- Analysis of meal and snack patterns of the children, including an estimation of the contribution of meals vs. snacks to nutrient intake
- Analysis of the nutrient content of packed lunches versus. school meals.
- The relationship between meal and snack frequency and dental health
- Association between the educational level of the main food provider and nutrient intake in the children

These studies have been funded by the FSAS.

### **11.3.3 Implications for health improvement**

The main finding of the present survey was that the intake of NMES as % food energy was much higher than recommended levels in the whole population and in all sub-groups. However, the foods consumed varied with socio-economic status, suggesting that different approaches may be needed to reduce the levels of NMES intake in different sectors of the population.

The results of the present survey can also be used to estimate the magnitude of dietary change needed to reach the dietary targets for NMES, total fat and saturated fatty acids. To meet the current dietary recommendations the intake of NMES (g/d) would have to decrease by 40% of present levels and the intake of saturated fatty acids (g/d) by 20% of present levels. To achieve this in the children in the present survey it would be necessary not only to remove all non-diet soft drinks, biscuits, cakes and pastries and confectionery from the diet but also to replace most of the energy provided by these foods by increasing the intake of other energy-providing foods, particularly foods rich in complex carbohydrate such as bread, potatoes, rice, and pasta. This would require major behaviour change in terms of meal composition, which would need to be supported by a wide range of initiatives addressing marketing and catering practices and nutrition knowledge and cooking skills of parents and children.

## Key points

- The impact of initiatives to improve the diet of Scottish children on NMES and total fat and saturated fatty acid intake could be monitored using the present survey data as a baseline
- Longitudinal studies in the participants in the present survey could help to identify whether higher intake of specific foods or of energy, sugar or fat increases the risk of weight gain.
- Longitudinal studies could also assess whether physical inactivity is a cause or a result of weight gain.
- While non-diet soft drinks, biscuits, cakes and pastries and confectionery are obvious targets for dietary change designed to reduce the intake of NMES and saturated fatty acids, increasing intake of foods rich in complex carbohydrates will also be needed.
- The types of interventions which will be needed to tackle the poor diet of children cover all links in the food chain, from production through marketing and food choice through to food preparation and meal patterns.

## Recommendations

Consideration should be given to repeating this survey at regular intervals to provide data on ongoing progress made towards Scottish Dietary targets for NMES and fat intake. Such a survey would also serve to evaluate the impact of policy initiatives directed at improving children's diet.

Research is needed to develop interventions to reduce intake of NMES and saturated fatty acids in children's diets to reach the Scottish Dietary Targets. In addition, measures need to be taken to ensure that a reduction in NMES and saturated fatty acids is complemented by an increase in foods rich in complex carbohydrate to provide a healthy, balanced diet.
